Connect-The-Dots: Identification of Heterogeneous Marginal Willingness to Pay Functions under Time-Varying
Preferences

Maria Juul Hansen ${ }^{1}$

${ }^{1}$ University of Copenhagen

## Overview

What? How can we identify and estimate MWTP for neighborhood amenities when preferences are time-varying?
Why? Valuation of neighborhood amenities important for allocation of public funds and for measuring benefits of regulation and traditional methods assume non-timevarying preferences when identifying MWTP
How? Developing hedonic model for two-purchase individuals and applying it to valuation of changes in violent crime

## Welfare analysis

## Conclusion

## Previous literature

- Rosen (1974) sets the stage for the hedonic theory that connects residential choices and associated house prices to WTP for neighborhood amenities
- Rosen's 2nd step: $P_{i}^{q}=\frac{\partial P_{i}}{\partial q_{i}}=\gamma_{0}+\gamma_{1} q_{i}+\gamma_{2}$
but well-known endogeneity problems due to sorting

## Previous literature

- Rosen (1974) sets the stage for the hedonic theory that connects residential choices and associated house prices to WTP for neighborhood amenities
- Rosen's 2nd step: $P_{i}^{q}=\frac{\partial P_{i}}{\partial q_{i}}=\gamma_{0}+\gamma_{1} q_{i}+\gamma_{2}$
but well-known endogeneity problems due to sorting
Figure 1: Picking $q$ to optimize utility with non-linear hedonic price

## Previous literature

- Rosen (1974) sets the stage for the hedonic theory that connects residential choices and associated house prices to WTP for neighborhood amenities
- Rosen's 2nd step: $P_{i}^{q}=\frac{\partial P_{i}}{\partial q_{i}}=\gamma_{0}+\gamma_{1} \boldsymbol{q}_{i}+\gamma_{2} \underbrace{w_{i}}_{\text {i's charcteristics }}+\underbrace{\epsilon_{i}}_{\text {unobs. pref. shock }}$
but well-known endogeneity problems due to sorting
Figure 1: Picking $q$ to optimize utility with non-linear hedonic price

## Avoiding the endogenous preference shock

- Bajari \& Benkard (2005): not estimating preferences in a traditional sense, but recovered at an individual level
- Preferences identified from conditions imposed by optimizing behaviour
- Individual heterogeneity embedded in parameters $\rightarrow$ no need for unobserved preference shock that caused endogeneity issues

## Solutions to Rosen's endogeneity problems using panel data

- Bishop \& Timmins (2018) extend the approach to identify both individual-specific intercepts and slopes of MWTP using data on individuals who are observed in two purchase occasions
- Requires that both purchases lie on the same demand curve - They assume preferences do not change over time to fulfill this - extension
- This paner: accounting for time-varving preferences by estimating $a_{2}$

## Solutions to Rosen's endogeneity problems using panel data

- Bishop \& Timmins (2018) extend the approach to identify both individual-specific intercepts and slopes of MWTP using data on individuals who are observed in two purchase occasions
- Requires that both purchases lie on the same demand curve - They assume preferences do not change over time to fulfill this - extension
- This paper: accounting for timevarying preferences by estimating $q_{2}$

## Overview

## The traditional approach and a few extensions

Alternative approach: Connect-The-Dots

## Data

## Results

## Welfare analysis

## Conclusion

## Estimation strategy

- Linear individual-specific MWTP for non-marginal changes in violent crime ( $q_{i t}$ )

$$
\begin{equation*}
M W T P_{q_{i t}}=\mu_{i 0}+\mu_{i 1} q_{i t} \tag{1}
\end{equation*}
$$

## Estimation strategy

- Linear individual-specific MWTP for non-marginal changes in violent crime ( $q_{i t}$ )

$$
\begin{equation*}
M W T P_{q_{i t}}=\mu_{i 0}+\mu_{i 1} q_{i t} \tag{1}
\end{equation*}
$$

## Step 1: Hedonic gradient

- Model does not rely on assumptions about shape of hedonic price
- Considered a function of amenity $q_{i t}$, housing and neighborhood attributes, $x_{i t}$ through the unknown function $g($.$) :$

$$
\begin{equation*}
P_{i t}=g\left(q_{i t}, x_{i t} ; \beta_{t}\right) \tag{2}
\end{equation*}
$$

- The implicit price for the amenity is:

$$
\begin{equation*}
\frac{d P_{i t}}{d q_{i t}} \equiv P_{i t}^{q} \tag{3}
\end{equation*}
$$

## Estimation strategy

## Step 2a: Segmentation equations

- Sorting in equilibrium leads to a segmentation of the market described by the relationship between $q$ and individual attributes (Mendelsohn (1985))
- Define the relationship between individual demographics $w_{i t}$ and violent crime $q_{i t}$ as

$$
\begin{equation*}
q_{i t}=f\left(w_{i t} ; \alpha_{i}, \delta_{t}\right) \tag{4}
\end{equation*}
$$

## Estimation strategy

Step 2b: Adjustment

- Adjust characteristics at second purchase back to values at first purchase: $w_{i 2} \rightarrow w_{i 1}$
- Predict demand for violent crime at second purchase had her characteristics not changed:

$$
\begin{equation*}
\tilde{q}_{i 2}=f\left(w_{i 1} ; \alpha_{i}, \hat{\delta}_{2}\right) \tag{5}
\end{equation*}
$$

- Compute implicit price she would have had to pay for $\tilde{q}_{i 2}$ :
- Demand for first purchase is observed and implicit price is:

## Estimation strategy

## Step 2b: Adjustment

- Adjust characteristics at second purchase back to values at first purchase: $w_{i 2} \rightarrow w_{i 1}$
- Predict demand for violent crime at second purchase had her characteristics not changed:

$$
\begin{equation*}
\tilde{q}_{i 2}=f\left(w_{i 1} ; \alpha_{i}, \hat{\delta}_{2}\right) . \tag{5}
\end{equation*}
$$

- Compute implicit price she would have had to pay for $\tilde{q}_{i 2}$ :
- Demand for first purchase is observed and implicit price is:

## Estimation strategy

## Step 2b: Adjustment

- Adjust characteristics at second purchase back to values at first purchase: $w_{i 2} \rightarrow w_{i 1}$
- Predict demand for violent crime at second purchase had her characteristics not changed:

$$
\begin{equation*}
\tilde{q}_{i 2}=f\left(w_{i 1} ; \alpha_{i}, \hat{\delta}_{2}\right) \tag{5}
\end{equation*}
$$

- Compute implicit price she would have had to pay for $\tilde{q}_{i 2}$ :

$$
\begin{equation*}
\tilde{P}_{i 2}^{\tilde{q}}=g^{\prime}\left(\tilde{q}_{i 2}, x_{i 2} ; \hat{\beta}_{2}\right) . \tag{6}
\end{equation*}
$$

- Demand for first purchase is observed and implicit price is:

## Estimation strategy

## Step 2b: Adjustment

- Adjust characteristics at second purchase back to values at first purchase: $w_{i 2} \rightarrow w_{i 1}$
- Predict demand for violent crime at second purchase had her characteristics not changed:

$$
\begin{equation*}
\tilde{q}_{i 2}=f\left(w_{i 1} ; \alpha_{i}, \hat{\delta}_{2}\right) \tag{5}
\end{equation*}
$$

- Compute implicit price she would have had to pay for $\tilde{q}_{i 2}$ :

$$
\begin{equation*}
\tilde{P}_{i 2}^{\tilde{q}}=g^{\prime}\left(\tilde{q}_{i 2}, x_{i 2} ; \hat{\beta}_{2}\right) . \tag{6}
\end{equation*}
$$

- Demand for first purchase is observed and implicit price is:

$$
\begin{equation*}
\tilde{P}_{i 1}^{q}=g^{\prime}\left(q_{i 1}, x_{i 1} ; \hat{\beta}_{1}\right) \tag{7}
\end{equation*}
$$

## Estimation strategy

## Step 3: MWTP function inversion

- In equilibrium, implicit price equals MWTP $\rightarrow$ two equations with two unknowns ( $\mu_{i 0}, \mu_{i 1}$ ):

$$
\begin{align*}
& \hat{P}_{i 1}^{q}=\mu_{i 0}+\mu_{i 1} q_{i 1}  \tag{8}\\
& \tilde{P}_{i 2}^{\tilde{q}}=\mu_{i 0}+\mu_{i 1} \tilde{q}_{i 2} \tag{9}
\end{align*}
$$

- Find the parameters of the MWTP function that "connect the dots" for each individual
- Identification requires variation in implicit prices and segmentation equations over time $\rightarrow$ panel data on home purchases, prices and buyers needed

## Estimation strategy

## Step 3: MWTP function inversion

- In equilibrium, implicit price equals MWTP $\rightarrow$ two equations with two unknowns ( $\mu_{i 0}, \mu_{i 1}$ ):

$$
\begin{align*}
& \hat{P}_{i 1}^{q}=\mu_{i 0}+\mu_{i 1} q_{i 1}  \tag{8}\\
& \tilde{P}_{i 2}^{\tilde{q}}=\mu_{i 0}+\mu_{i 1} \tilde{q}_{i 2} \tag{9}
\end{align*}
$$

- Find the parameters of the MWTP function that "connect the dots" for each individual
- Identification requires variation in implicit prices and segmentation equations over time $\rightarrow$ panel data on home purchases, prices and buyers needed

## Estimation strategy

## Step 3: MWTP function inversion

- In equilibrium, implicit price equals MWTP $\rightarrow$ two equations with two unknowns ( $\mu_{i 0}, \mu_{i 1}$ ):

$$
\begin{align*}
& \hat{P}_{i 1}^{q}=\mu_{i 0}+\mu_{i 1} q_{i 1}  \tag{8}\\
& \tilde{P}_{i 2}^{\tilde{q}}=\mu_{i 0}+\mu_{i 1} \tilde{q}_{i 2} \tag{9}
\end{align*}
$$

- Find the parameters of the MWTP function that "connect the dots" for each individual
- Identification requires variation in implicit prices and segmentation equations over time $\rightarrow$ panel data on home purchases, prices and buyers needed

## Overview

Data

Results

Welfare analysis

Conclusion

## Data sources

- Danish register data on demographics of the entire population of individuals and households for the period 2008-2014
- Sales prices for the population of transacted houses and housing characteristics (location, size, rooms...) of all houses
- Home ownership that allows me to link demographic data to housing data via SSN and house id
- Amenities: number of victims of violent and property crime and school districts
- Police reports with info on detailed type of crime, location and time of incidence
- Violent crime: serious violent crime, rape, crime against life and body, murder, attempted murder, violence against public authorities (exclude: simple violence, threats, crime against personal freedom)
- Property crime: thefts and robberies (exclude: blackmailing)

## Data sample

- Restrict to parishes in Copenhagen local labor market 2008-2014 and exclude renters, private sales only
- Parishes: admin units that assign individuals to a local church. 2017 version: 294 parishes
- $\Rightarrow \sim 95,000$ buyers, $\sim 59,000$ housing transactions, $\sim 2,600$ repeat

Figure 3: Copenhagen local labor market and average violent crime 2008-2014

## Overview

# The traditional approach and a few extensions 

Alternative approach: Connect-The-Dots

Data

## Results

## Welfare analysis

Conclusion

## Empirical specification: Step 1 - Hedonic gradient

- Estimate gradient semi-parametrically using Robinson's method

$$
\begin{equation*}
P_{i t}\left(q_{i t}, x_{i t} ; \beta_{t}\right)=x_{i t}^{\prime} \beta_{t}^{x}+\Lambda\left(q_{i t} ; \beta_{t}\right)+\epsilon_{i t} \tag{10}
\end{equation*}
$$

- $q_{i t}$ : violent crime pr. 1,000 inhabitants
- $\Lambda($.$) : flexible function of q_{i t}$ (end up using local linear function w. bw $2.5 \cdot s d\left(q_{i t}\right)$, adaptive bw 0$)$
- $\epsilon_{i t}$ : regression error
- $x_{i t}$ : vector of other housing or neighborhood attributes
- quadratic functions of the property crime rate, square meters sold and number of rooms
- dummy variables for bathroom, kitchen, apartment
- school district fixed effects

## Results: Step 1 - Hedonic gradient

Figure 4: Results of 1st Stage by Year, $P_{t}\left(q_{i, t}\right)$
(a) Hedonic price function
(b) Hedonic gradient

Note: The violent crime rate is measured as number of victims of violent crime per 1,000 people.

- Hedonic price function is positive and slopes downwards
- I.e. negative gradient (safety is a good) and shows variability over time

## Results: Step 1 - Hedonic gradient

Figure 4: Results of 1st Stage by Year, $P_{t}\left(q_{i, t}\right)$
(a) Hedonic price function
(b) Hedonic gradient

Note: The violent crime rate is measured as number of victims of violent crime per 1,000 people.

- Hedonic price function is positive and slopes downwards
- I.e. negative gradient (safety is a good) and shows variability over time
- But gradients slope upwards as usually found in the literature.
- This is the simple measure of WTP often found in the literature (high crime areas: lower WTP for reductions)

## Results: Step 2 - Segmentation

Table 1: Segmentation equation for violent crime rate

| Year FE | No | No | No | No | Yes |
| Individual FE | Yes | Yes | Yes | Yes | Yes |

- Consumption of violent crime tends to drop over time and with children

## Results: Step 2 - Segmentation

- Children have an economically significant effect on demand
- 2008, 0 children: demand is 0.818
- 2008, 1 child: demand is $0.818-0.352$
- Income, debt, assets, divorce don't have any significant effects once controlling for individual FE
- Individual FE account for a significant share of the variation

## Results: Step 2 - Segmentation

- Children have an economically significant effect on demand
- 2008, 0 children: demand is 0.818
- 2008, 1 child: demand is $0.818-0.352$
- Income, debt, assets, divorce don't have any significant effects once controlling for individual FE
- Individual FE account for a significant share of the variation

Figure 5: Distribution of fixed effects in demand for violent crime

## Results: Step 3 - Inversion

- With demand estimated for the 2nd purchase, the implicit price is found by using nearest neighbor interpolation of the gradient function in that year
- $\rightarrow$ two points on the same demand curve

$$
\begin{gather*}
\hat{\mu}_{i 1}=\frac{\tilde{P}_{i 2}^{\tilde{q}}-\hat{P}_{i 1}^{q}}{\tilde{q}_{i 2}-q_{i 1}}  \tag{11}\\
\hat{\mu}_{i 0}=\hat{P}_{i 1}^{q}-\hat{\mu}_{i 1} q_{i 1} \tag{12}
\end{gather*}
$$

## Summary of results

Figure 6: CTD: Distribution of $\hat{\mu}_{1}$ and negative MWTP

$$
\text { (a) } \mu_{1}
$$

(b) -MWTP for violent crime

Note: Removing individuals with the $5 \%$ most extreme estimates of MWTP. Violent crime measured as number of victims of violent crime per 1,000 people.

- $\hat{\mu_{1}}<0$ as expected
-     - MWTP $>0$ and in the range 200,000-550,000 DKK ( $\approx 30,000-80,000$ USD)
- Peaks in MWTP distribution reflect heterogeneity from children and time

## Results using Rosen

- Get hedonic gradient for each individual at observed crime levels using interpolation
- Regress hedonic gradient on individual attributes, fixed effects and crime
- positive slope: individauls $w$. high $q$ have lower MWTP for reductions $\rightarrow$ biased Rosen 2nd stage

## Overview

The traditional approach and a few extensions

Alternative approach: Connect-The-Dots

Data

## Results

## Welfare analysis

## Conclusion

## Welfare analysis

- WTP to avoid a $30 \%$ increase in violent crime using CTD vs Rosen's approach - Details
- Generally find that MWTP is increasing in violent crime using CTD
- Rosen: suffers from a bias implying decreasing MWTP as crime increases (demand for safety is upward-sloping)
- Rosen: overstates the WTP for a reduction in crime and understates the WTP to avoid an increase in crime

## Welfare analysis

- WTP to avoid a $30 \%$ increase in violent crime using CTD vs Rosen's approach Details
- Generally find that MWTP is increasing in violent crime using CTD
- Rosen: suffers from a bias implying decreasing MWTP as crime increases (demand for safety is upward-sloping)
- Rosen: overstates the WTP for a reduction in crime and understates the WTP to avoid an increase in crime

Figure 7: Example: computing WTP using different methods

Figure 7: Example: computing WTP using different methods

## Welfare analysis: Rosen's bias

- Significant (Epple-style) bias in WTP when using Rosen's method despite taking individual heterogeneity into account
- Bias in the range 0 to $-100,000$ DKK ( $\approx 0$ to $-15,000$ USD)
- Understatement of the cost of crime of up to $-70 \%$ (-24.4\% on average)

Figure 8: Bias of Rosen's negative WTP for a $30 \%$ increase in violent crime
(a) $10,000 \mathrm{DKK}$
(b) $\%$ difference

Note: The violent crime rate is measured as number of victims of violent crime per 1,000 people.

## Welfare analysis: Rosen's bias by crime level

Figure 9: Bias of Rosen's negative WTP for a $30 \%$ increase in violent crime

## Welfare analysis: Rosen's bias by crime level

- Bias in cost of crime even larger for households living in high-crime areas

Figure 9: Bias of Rosen's negative WTP for a $30 \%$ increase in violent crime

## Welfare analysis: Rosen's bias by crime level

- Bias in cost of crime even larger for households living in high-crime areas
- In most crime-intensive areas, bias is up to -500,000 DKK (-72,000 USD)

Figure 9: Bias of Rosen's negative WTP for a $30 \%$ increase in violent crime

## Welfare analysis: Rosen's bias by crime level

- Bias in cost of crime even larger for households living in high-crime areas
- In most crime-intensive areas, bias is up to -500,000 DKK (-72,000 USD)
- $\rightarrow$ concern from policy-perspective: Rosen's method understates the costs of crime increases more in high-crime areas (where reductions needed) than in safer areas

Figure 9: Bias of Rosen's negative WTP for a $30 \%$ increase in violent crime

## Welfare analysis: Rosen's bias by crime level

- Bias in cost of crime even larger for households living in high-crime areas
- In most crime-intensive areas, bias is up to -500,000 DKK (-72,000 USD)
- $\rightarrow$ concern from policy-perspective: Rosen's method understates the costs of crime increases more in high-crime areas (where reductions needed) than in safer areas
- $\rightarrow$ if not accounting for this bias, welfare-burden of the bias would fall more heavily on high-crime areas (often disadvantaged households)
Figure 9: Bias of Rosen's negative WTP for a $30 \%$ increase in violent crime

## Overview

The traditional approach and a few extensions

Alternative approach: Connect-The-Dots

Data

## Results

## Welfare analysis

## Conclusion

## Conclusions

- Traditional hedonic methods only provide valid approximations of the WTP for marginal changes in (dis)amenities. Most policy-relevant changes tend to be non-marginal
- Accurately recovering the entire MWTP function is therefore important, but the literature has struggled with how to do this
- I develop a method that identifies both heterogeneous intercepts and slopes of individual MWTP functions while allowing for time-varying preferences
- I compare estimated WTP for large increases in violent crime to estimates using the traditional approach from Rosen (1974)
- I find that the traditional method severely understates the costs of $30 \%$ increases in crime by up to $70 \%$ and $24.4 \%$ on average
- This understatement is worse in high-crime areas
- Policy-makers should account for this bias and the heterogeneity in WTP when designing optimal policies

## Overview

Appendix

## Rosen's approach

- The slope of the indifference curve in $(q, P)$ space reflects the willingness to give up an additional unit of other consumption in exchange for more $q$
- That point on the slope of the hedonic price function reveals the otherwise unobserved slope of their indifference curve
- Estimate MWTP function in 2nd step as a function of $q \rightarrow$ measure value of non-marginal change in $q$ :

Figure 10: Picking $q$ to optimize utility

## Rosen's approach

## Rosen's approach

- The slope of the indifference curve in $(q, P)$ space reflects the willingness to give up an additional unit of other consumption in exchange for more $q$
- That point on the slope of the hedonic price function reveals the otherwise unobserved slope of their indifference curve
- Estimate MWTP function in 2nd step as a function of $q \rightarrow$ measure value of non-marginal change in $q$ :

$$
P_{i}^{q}=\frac{\partial P_{i}}{\partial q_{i}}=\gamma_{0}+\gamma_{1} q_{i}+\gamma_{2} \underbrace{w_{i}}_{\text {i's charcteristics }}+\underbrace{\epsilon_{i}}_{\text {unobs. pref. shock }}
$$

Figure 10: Picking $q$ to optimize utility

## Problems with Rosen's approach

- When individuals sort along the hedonic price function $P(q)$, they both choose the level of $q$ and the implicit price $P_{i}^{q}$
- Non-linear hedonic price: high unobserved preferences $\epsilon_{i}$ for $q \rightarrow$ high value of $q$ and a high implicit price (if $P(q)$ is convex)
- $\rightarrow \epsilon_{i}$ is correlated with $q_{i}$ and $P_{i}^{q}$

## Problems with Rosen's approach

Figure 11: Picking $q$ to optimize utility with non-linear hedonic price

- When individuals sort along the hedonic price function $P(q)$, they both choose the level of $q$ and the implicit price $P_{i}^{q}$
- Non-linear hedonic price: high unobserved preferences $\epsilon_{i}$ for $q \rightarrow$ high value of $q$ and a high implicit price (if $P(q)$ is convex)
- $\rightarrow \epsilon_{i}$ is correlated with $q_{i}$ and $P_{i}^{q}$

## Problems with Rosen's approach

Figure 11: Picking $q$ to optimize utility with non-linear hedonic price

- When individuals sort along the hedonic price function $P(q)$, they both choose the level of $q$ and the implicit price $P_{i}^{q}$
- Non-linear hedonic price: high unobserved preferences $\epsilon_{i}$ for $q \rightarrow$ high value of $q$ and a high implicit price (if $P(q)$ is convex)

## Problems with Rosen's approach

Figure 11: Picking $q$ to optimize utility with non-linear hedonic price

- When individuals sort along the hedonic price function $P(q)$, they both choose the level of $q$ and the implicit price $P_{i}^{q}$
- Non-linear hedonic price: high unobserved preferences $\epsilon_{i}$ for $q \rightarrow$ high value of $q$ and a high implicit price (if $P(q)$ is convex)
- $\rightarrow \epsilon_{i}$ is correlated with $q_{i}$ and $P_{i}^{q}$

## Solutions to Rosen's endogeneity problems

- Bajari \& Benkard (2005) invented an approach where preferences are not estimated in a traditional sense, but recovered at an individual level
- Individual preference parameters are identified from the conditions imposed by optimizing behaviour

$$
\begin{equation*}
\max _{q, x, c} U(q, x ; k)=k_{1, i} q+k_{2, i} x+c \text {, s.t. } c+P(q, x)=1 \tag{13}
\end{equation*}
$$

- Solve for indirect utility $V$ and solve FOC wrt. $(q, x)$

$$
\begin{equation*}
\frac{\partial V_{i}}{\partial q}: \underbrace{\kappa_{1, i}}_{\text {MWTP }}=\underbrace{\frac{\partial P}{\partial q}}_{\text {observed }} \tag{14}
\end{equation*}
$$

- Individual heterogeneity is embedded in parameters. This avoids the need for an unobserved preference shock that caused endogeneity issues
- But rely on functional form assumptions to identify MWTP function from just one observation of $(P, q)$

## Solutions to Rosen's endogeneity problems

- Bajari \& Benkard (2005) invented an approach where preferences are not estimated in a traditional sense, but recovered at an individual level
- Individual preference parameters are identified from the conditions imposed by optimizing behaviour

$$
\begin{equation*}
\max _{q, x, c} U(q, x ; \kappa)=\kappa_{1, i} q+\kappa_{2, i} x+c, \text { s.t. } c+P(q, x)=I \tag{13}
\end{equation*}
$$

- Solve for indirect utility $V$ and solve FOC wrt. $(q, x)$

- Individual heterogeneity is embedded in parameters. This avoids the need for an unobserved preference shock that caused endogeneity issues
- But rely on functional form assumptions to identify MWTP function from just one observation of $(P, q)$

## Solutions to Rosen's endogeneity problems

| Build year | 1956 | 33.02 | 1963 | 58,542 |  |  |
| \# rooms | 4.02 | 1.39 | 4.00 | 58,920 |  |  |
| Km to Copenhagen center | 17.23 | 13.47 | 12.61 | 58,920 |  |  |
| Inhabs. pr. km $^{2}$ | 3,748 | 5,456 | 1,720 | 58,920 |  |  |

Sample criteria: Only using one property observation within the household in the year. Note: $\mathbb{I}$ is the indicator function.

## Summary stats (buyers)

Table 3: Summary statistics of buyers at time of purchase by total number of purchases

|  | Mean | S.d | N |
| :--- | :---: | :---: | :---: |
| 1 purchase |  |  |  |
| Age | 38.85 | 11.94 | 92,121 |
| $\mathbb{I}[$ couple] | 0.83 | 0.38 | 92,121 |
| $\mathbb{I}[$ male] | 0.50 | 0.50 | 92,121 |
| $\mathbb{I}[$ has children] | 0.56 | 0.50 | 92,121 |
| $\mathbb{I}[$ has school age child] | 0.23 | 0.42 | 92,121 |
| Education |  |  |  |
| $\quad$ Unskilled | 0.04 | 0.18 | 92,121 |
| $\quad$ High school | 0.17 | 0.38 | 92,121 |
| $\quad$ Vocational/Short Cycle Tertiary | 0.25 | 0.43 | 92,121 |
| $\quad$ Medium Cycle Tertiary | 0.29 | 0.45 | 92,121 |
| $\mathbb{I}[$ divorce | 0.03 | 0.17 | 76,408 |
| Household total inc. (10t DKK) | 76.03 | 27.44 | 83,036 |
| Household assets (10t DKK) | 272.48 | 113.21 | 82,916 |
| Household debt (10t DKK) | 248.18 | 159.49 | 92,101 |
| $\mathbb{I}[$ new job municipality] | 0.37 | 0.48 | 92,121 |
| $\mathbb{I}[$ live in big city] | 0.54 | 0.50 | 92,121 |

Note: $\mathbb{I}$ is the indicator function. $\mathbb{I}[$ new job municipality $]=1$ if either or both of the household members gets a job in $t$ in another municipality than where they had a job in $t-1$. Monetary terms deflated by 2011 consumer price index.

## Summary stats (buyers)

Table 4: Summary statistics of buyers at time of purchase by total number of purchases

|  | Mean | S.d | N |
| :--- | :---: | :---: | :---: |
| 2 purchases, 1st purchase |  |  |  |
| Age | 34.70 | 9.99 | 2,670 |

| $\mathbb{I}[$ live in big city] | 0.54 | 0.50 | 2,670 |

Note: $\mathbb{I}$ is the indicator function. $\mathbb{I}[$ new job municipality $]=1$ if either or both of the household members gets a job in $t$ in another municipality than where they had a job in $t-1$. Monetary terms deflated by 2011 consumer price index.

## Additional summary stats

- Parishes per school district: mean 2, median 4, max. 14
- School district size $\left(\mathrm{km}^{2}\right)$ : mean 26 , median 20 , max. 122 , min. 1
- Parish size $\left(\mathrm{km}^{2}\right)$ : mean 9.7 , median 7.0 , max 49.3 , min. 0.1

## Robinson 2-step estimation

For each year:

1. Estimate $\mathbb{E}\left[a_{i t} \mid q_{i t}\right], a_{i t} \in\left\{x_{i t}, p_{i t}\right\}$ using non-parametric regression of $x_{i t}$ controls and price $p_{i t}$ on $q_{i t}$. Compute predicted value and then residuals.
2. OLS of residualized $p_{i t}$ on residualized $x_{i t}$ from 1) (consistent estimates of effect of $x_{i t}$ on $p_{i t}, \beta_{t}^{\times}$). Compute predicted value and subtract from observed $p_{i t}$ to get residual.
3. Non-parametric regression of residualized $p_{i t}$ from 2) on $q_{i t}$.
4. For plotting hedonic price, use (10) evaluated for each data point $q_{i t}$ and level shifted with predicted mean of $x_{i t}^{\prime} \beta_{t}^{x}$ (i.e. using predicted value from 1) at each data point for $q_{i t}$ )

## Distribution estimates of $m u_{0}$

Figure 13: CTD: Results of Inversion for $\mu_{0}$
(a) $\mu_{0}$

Note: Removing individuals with the $5 \%$ most extreme estimates of MWTP. Violent crime measured as number of victims of violent crime per 1,000 people.

## Results: Rosen 2nd stage

Table 6: Rosen 2nd stage: OLS of MWTP with individual fixed effects

## Computing WTP of redcution from $q_{0}$ to $q_{\text {low }}$

- MWTP using CTD:

$$
\begin{equation*}
M W T P_{i t}^{C T D}=\mu_{i 0}+\mu_{i 1} q_{i t} \tag{15}
\end{equation*}
$$

- WTP to avoid an increase in violent crime for $i$ is then calculated for each individual by

$$
\begin{align*}
W T P_{i t}^{C T D} & =-\int_{q_{h i g h}}^{q_{0}}\left(\mu_{i 0}+\mu_{i 1} q\right) d q \\
& =-\left(\mu_{i 0} \cdot\left(q_{i t, h i g h}-q_{i t, 0}\right)+0.5 \cdot \mu_{i 1}\left(q_{i t, h i g h}^{2}-q_{i t, 0}^{2}\right)\right) \tag{16}
\end{align*}
$$

- MWTP using Rosen:

$$
\begin{equation*}
M W T P_{i t}^{R}=\alpha_{0}+\alpha_{1} \cdot q_{i t}+\epsilon_{i t} \tag{17}
\end{equation*}
$$

- WTP using Rosen:

$$
\begin{equation*}
W T P_{i t}^{R}=-\left(\alpha_{0} \cdot\left(q_{i t, h i g h}-q_{i t, 0}\right)+0.5 \cdot \alpha_{1}\left(q_{i t, h i g h}^{2}-q_{i t, 0}^{2}\right)\right) \tag{18}
\end{equation*}
$$
