## Forecasting with panel data: Estimation uncertainty versus parameter heterogeneity

Hashem Pesaran - USC and Trinity College, Cambridge Andreas Pick - Erasmus University Rotterdam, TI, DNB Allan Timmermann - UCSD, CEPR and CREATES

ESEM, August 2022

#### Focus and agenda

- Panel literature focuses on parameter estimation and inference
  - Surprisingly few studies on using panel estimation to forecast individual units, see Baltagi (2013)
- We examine existing approaches and develop new forecasting methods for panel data with heterogeneous parameters
  - new forecast poolability test which we contrast with parameter homogeneity tests
  - new forecast combination methods
- We compare the predictive accuracy of individual forecasts for different cross-sectional (*N*) and time (*T*) dimensions, and varying degrees of parameter heterogeneity

#### Panel data models with parameter heterogeneity

• Baseline panel model

 $y_{it} = \beta'_i \mathbf{x}_{it} + \varepsilon_{it}, \quad i = 1, 2, \dots, N, \ t = 1, 2, \dots, T$ 

- We study forecast of individual units, *y*<sub>*it*</sub>, given the ex-ante known predictors, *x*<sub>*it*</sub>
- Forecasts can be computed using individual estimates of  $\beta_i$  or using the pooled estimate  $\beta_i = \beta$

・ロト ・ 理 ト ・ ヨ ト ・ ヨ ト

#### Comparing MSFE values: Individual vs. pooled

• Forecasts based on individual estimates:

$$\begin{aligned} \hat{y}_{i,T+1} &= \hat{\beta}'_{i} \mathbf{x}_{i,T+1}, & \hat{\beta}_{i} &= (\mathbf{X}'_{i} \mathbf{X}_{i})^{-1} \mathbf{X}'_{i} \mathbf{y}_{i}, \\ \hat{e}_{i,T+1} &= y_{i,T+1} - \hat{y}_{i,T+1}. \end{aligned}$$

• Forecasts based on pooled estimator:

$$\begin{split} \tilde{y}_{i,T+1} &= \tilde{\boldsymbol{\beta}}' \boldsymbol{x}_{i,T+1}, \\ \tilde{e}_{i,T+1} &= y_{i,T+1} - \tilde{y}_{i,T+1}. \end{split}$$

・ロト ・ 母 ト ・ ヨ ト ・ ヨ

#### Proposition 1

(i) The MSFE from individual-specific parameter estimation is

$$\begin{aligned} \operatorname{Var}(\hat{e}_{i,T+1}|\boldsymbol{X}_{i},\boldsymbol{x}_{i,T+1}) &= \sigma_{i}^{2} + T^{-1}\sigma_{i}^{2}\boldsymbol{x}_{i,T+1}^{\prime}\boldsymbol{Q}_{iT}^{-1}\boldsymbol{x}_{i,T+1} \\ &= \sigma_{i}^{2} + O_{p}\left(T^{-1}\right), \end{aligned}$$

where  $\mathbf{Q}_{iT} = T^{-1} \mathbf{X}'_i \mathbf{X}_i$ . (ii) The MSFE from pooled parameter estimation is

 $\operatorname{Var}(\tilde{e}_{i,T+1}|\boldsymbol{X}_{i},\boldsymbol{x}_{i,T+1}) = \sigma_{i}^{2} + \boldsymbol{x}_{i,T+1}^{\prime}\boldsymbol{\Omega}_{\eta}\boldsymbol{x}_{i,T+1} + O_{p}\left(N^{-1}\right).$ 

(日)

#### Interpretation of Proposition

- Remark 1 For small *T*, parameter estimation uncertainty can be important for the *individual* forecasts. Parameter heterogeneity, in contrast, does not affect the accuracy of the individual forecasts. For large *T*, forecasts based on individual estimation will have a lower MSFE than forecasts based on pooled estimation.
- Remark 2 The accuracy of forecasts that use pooled estimates depends both on the degree of parameter heterogeneity and the dispersion of the predictors through  $x'_{i,T+1}\Omega_{\eta}x_{i,T+1}$ .
- Remark 3 Forecasts based on *individual* estimates have large *T* optimality properties even if predictors are weakly exogenous. In contrast, forecasts based on *pooled* regressions require strict exogeneity.
- Remark 4 Parameter heterogeneity could be particularly problematic if  $\eta_i = \beta_i E(\beta_i)$ and  $X'_i X_i$  are correlated. *Individual* estimates of  $\beta_i$  are not affected by parameter heterogeneity even if heterogeneity is correlated with  $x_{it}$ . The same is *not* true for the *pooled* estimates:  $\lim_{N \to \infty} (\tilde{\beta} - \beta) = \Psi^{-1}b$ , where

$$\Psi = \lim_{N \to \infty} N^{-1} \sum_{i=1}^{N} \mathbb{E} \left( \mathbf{X}_{i}^{\prime} \mathbf{X}_{i} \right), \quad \mathbf{b} = \lim_{N \to \infty} N^{-1} \sum_{i=1}^{N} \mathbb{E} \left( \mathbf{X}_{i}^{\prime} \mathbf{X}_{i} \boldsymbol{\eta}_{i} \right).$$

For the pooled estimator to be unbiased, need that  $E(X'_iX_i\eta_i) = 0$ .

・ロト ・ 四ト ・ ヨト ・ ヨト - - ヨ

#### **Combination forecasts**

Consider the combined forecast

 $\mathbf{y}_{i,T+1}^* = \omega_i \hat{\mathbf{y}}_{i,T+1} + (1 - \omega_i) \tilde{\mathbf{y}}_{i,T+1},$ 

with forecast error

 $e_{i,T+1}^* = \omega_i \hat{e}_{i,T+1} + (1 - \omega_i)\tilde{e}_{i,T+1}.$ 

The optimal  $\omega_i^*$ , which minimizes the MSFE of the combined forecast is

$$\omega_i^* = \frac{\operatorname{Var}(\tilde{e}_{i,T+1}) - \operatorname{Cov}(\hat{e}_{i,T+1}, \tilde{e}_{i,T+1})}{\operatorname{Var}(\hat{e}_{i,T+1}) + \operatorname{Var}(\tilde{e}_{i,T+1}) - 2\operatorname{Cov}(\hat{e}_{i,T+1}, \tilde{e}_{i,T+1})}$$

(日)

### Optimal combination weights

#### Proposition 2

For fixed  $T > T_0$ , the optimal combination weights that minimize the MSFE conditional on  $X_i$  and  $x_{i,T+1}$ ,  $\Omega_\eta$  and  $\sigma_i^2$  are given by (for i = 1, 2, ..., N)

$$\omega_{i}^{*} = \frac{\boldsymbol{x}_{i,T+1}^{\prime}\boldsymbol{\Omega}_{\eta}\boldsymbol{x}_{i,T+1}}{\boldsymbol{x}_{i,T+1}^{\prime}\left[T^{-1}\sigma_{i}^{2}\boldsymbol{Q}_{iT}^{-1} + \boldsymbol{\Omega}_{\eta}\right]\boldsymbol{x}_{i,T+1}} + O_{p}\left(N^{-1}\right)$$

#### Bias-adjusted combination weights

We use the following bias-adjusted plug-in estimator for  $\omega_i^*$ 

$$\tilde{\omega}_{i}^{*} = \frac{\boldsymbol{x}_{i,T+1}^{\prime} \left[ \hat{\boldsymbol{\Omega}}_{\eta} - \frac{1}{NT} \sum_{i=1}^{N} \hat{\sigma}_{i}^{2} \boldsymbol{Q}_{iT}^{-1} \right] \boldsymbol{x}_{i,T+1}}{\boldsymbol{x}_{i,T+1}^{\prime} \left[ \frac{1}{T} \hat{\sigma}_{i}^{2} \boldsymbol{Q}_{iT}^{-1} + \hat{\boldsymbol{\Omega}}_{\eta} - \frac{1}{NT} \sum_{i=1}^{N} \hat{\sigma}_{i}^{2} \boldsymbol{Q}_{iT}^{-1} \right] \boldsymbol{x}_{i,T+1}}$$

Weights are restricted to lie between zero and one

#### Forecast-based tests for pooling

From the expressions for the MSFE of the individual and pooled forecasts

$$\begin{split} \mathsf{MSFE}(\hat{y}_{i,T+1}) &- \mathsf{MSFE}(\tilde{y}_{i,T+1}) \\ &= T^{-1} \sigma_i^2 \boldsymbol{x}_{i,T+1}' \boldsymbol{Q}_{iT}^{-1} \boldsymbol{x}_{i,T+1} - \boldsymbol{x}_{i,T+1}' \ \boldsymbol{\Omega}_{\eta} \boldsymbol{x}_{i,T+1} + O_p \left( N^{-1} \right) . \end{split}$$

A D N A B N A B N A B

### New pre-test for pooling

#### **Proposition 3**

Suppose that  $\eta_i$  and  $\varepsilon_i$  are normally distributed, and  $\eta_i$  are cross-sectionally independent. Then, under the null of equal forecast accuracy defined by

 $H_{0,PF}: T^{-1}\sigma_{i}^{2} \mathbf{x}_{i,T+1}^{\prime} \mathbf{Q}_{iT}^{-1} \mathbf{x}_{i,T+1} = \mathbf{x}_{i,T+1}^{\prime} \mathbf{\Omega}_{\eta} \mathbf{x}_{i,T+1}, \quad \forall i,$ 

there exists a finite  $T_0$  such that for all  $T>T_0$  and as  $N
ightarrow\infty$ 

$$PF_{NT} = rac{1}{\sqrt{N}} \sum_{i=1}^{N} \left( rac{\omega_{i,NT}^2 - 1}{\sqrt{2}} 
ight) \stackrel{d}{
ightarrow} \mathrm{N}(0,1),$$

where

$$\omega_{i,NT}^2 = \frac{T\left[\mathbf{x}_{i,T+1}'(\hat{\boldsymbol{\beta}}_i - \bar{\hat{\boldsymbol{\beta}}})\right]^2}{2\sigma_{i,NT}^2 \mathbf{x}_{i,T+1}' \mathbf{Q}_{iT}^{-1} \mathbf{x}_{i,T+1}}.$$

A D N A B N A B N A B

#### Monte Carlo: Design

$$\mathbf{y}_{i,t+1} = \alpha_i + \rho_i \mathbf{y}_{it} + \gamma_i \mathbf{x}_{it} + \kappa \sigma_i \varepsilon_{i,t+1},$$

$$\varepsilon_{i,t+1} \sim \operatorname{iidN}(0,1), \quad \sigma_i^2 \sim \operatorname{iid}(1+\chi_1^2)/2$$

$$x_{it} = \mu_{xi} + \xi_{it}, \quad \mu_{xi} = (z_i^2 - 1)/\sqrt{2}, \quad z_i \sim \mathrm{iidN}(0, 1),$$

$$\xi_{it} = \rho_{xi}\xi_{i,t-1} + \sigma_{xi}\left(1 - \rho_{xi}^2\right)^{1/2}\nu_{it}, \quad \nu_{it} \sim \operatorname{iidN}\left(0,1\right),$$

 $\sigma_{xi}^2 \sim \text{iid}(1 + \chi_1^2) / 2.$ 

N = 500 and  $T = \{20, 50, 100\}$ . Number of replications:  $\mathcal{R} = 10,000$ .

#### Monte Carlo (cont.)

- Autocorrelations of  $x_{it}$ :  $\rho_{xi} \sim \text{iid Uniform}(0, 0.95)$
- Coefficient of  $y_{i,t-1}$ :  $\rho_i \sim \text{iid Uniform}(0, \bar{\rho})$ , where we vary  $\bar{\rho}$  to capture different degrees of dynamic heterogeneity. The value of  $\bar{\rho}$  depends on the value of pooled  $\mathbb{R}^2$ .
- We consider cases where the regressors and the coefficients are correlated:

 $\alpha_i = \phi \mu_{xi} + \sigma_\eta \eta_i$ , and  $\gamma_i = 1 + \theta \mu_{xi} + \sigma_\zeta \zeta_i$ ,

where  $\eta_i, \zeta_i \sim \text{iidN}(0, 1)$ .

(日)

### List of Panel Forecasting Methods

- Individual estimation
- Pooled estimation
- Random effects estimator of Goldberger (1962)
- Median group estimator (new)
- Forecast combination with bias-unadjusted and bias-adjusted weights
- Forecasts based on the pre-test (poolability test)
- Forecasts based on the shrinkage estimators (Maddala et al. (1997)):
  - prior likelihood
  - Bayesian
  - empirical Bayes

Measures of Predictive Accuracy: Median of individual MSFEs

< □ > < □ > < □ > < □ > < □ >

Results

#### Some Monte Carlo Results

- Pooled estimates perform best:
  - under parameter homogeneity
  - when average  $R^2$  is low and *T* is relatively small, T = 20, even in the presence of parameter heterogeneity.
  - in the absence of correlated heterogeneity
- Forecast combination using  $\hat{\Omega}_{\eta}$  is the most precise method more often than any other methods, and is otherwise close to the best forecast. It is also robust to correlation between parameters and regressors.
- Pre-test forecasts, using the poolability test, consistently chooses best of individual and pooled forecasts.
- Shrinkage forecasts perform well under parameter homogeneity, but have a mixed performance under parameter heterogeneity
- Conclusion: No uniform ordering of the forecasting methods due to the tradeoffs between estimation uncertainty and parameter heterogeneity

・ロト ・ 日 ・ ・ ヨ ・ ・ ヨ ・

### **Empirical Applications**

Three empirical applications:

- In the second second
- Inflation of CPI sub-indices
- stock returns on U.S. firms.

Contrasting in-sample fit:

- individual stock returns: in-sample  $R^2 < 0.01$
- CPI: in-sample  $R^2 \approx 0.2$
- house price inflation in-sample  $R^2 \approx 0.8$

#### Stock returns

- Panel of 23,121 individual US firm-level monthly stock returns
- Sample from January 1977 through December 2017
- Rolling estimation window of 120 observations; out-of-sample forecasts from January 1987 through December 2017 given period, between 1,116 and 2,726 stocks are included

 $y_{i,t+1} = \alpha_i + \beta_i x_{it} + \varepsilon_{it+1},$ 

•  $x_{it}$  is the 6-month momentum of stock *i*, measured using cumulative returns up to the previous month

#### Conclusion

- Comprehensive examination of the out-of-sample predictive accuracy of a large set of existing and novel panel data methods
- Main findings:
  - Several approaches perform systematically better than individual forecasts: sizeable gains from exploiting panel information
  - No single forecasting approach is uniformly dominant across applications. Yet, combination and (Bayesian) shrinkage forecasts are more precise than the pooled and individual forecasts
  - Methods differ in risk profiles: individual, pooled, random effect, and median group methods do poorly in at least one application
- Forecast combinations and shrinkage methods offer insurance against poor performance. Forecast combinations, in particular, perform well across the board, the performance of shrinkage methods tends to vary a bit more across applications
