# Income, Employment and Health Risks of Older Workers 

Siqi Wei
CEMFI

22 Aug 2022
EEA-ESEM 2022

## Motivation

- Meet Dennis, a 58 -year-old software engineer
- He has a well-paying but stressful job in a high-tech company
- He is considering moving to a worse-paying but less demanding job (e.g., part-time teacher in a school)
- His plan is to work there a few more years before fully retiring
- For many older Americans, retirement is not a one-time withdrawal from the labor market, but a gradual process.
- Around $30 \%-50 \%$ of older workers in the United States experience post-retirement employment (loosely called bridge jobs) before exiting the labor force for good
- Gradual transition to full retirement often involves moving to jobs with
- Less salary
- Fewer working hours

## Motivation

- Age $\uparrow \Rightarrow$ left-skewness of earning and hour changes for job movers $\uparrow$

(a) Log earning changes of job movers by age group

(b) Log hour changes of job movers by age group

## This Paper

1. Explain the gradual transition:

- Propose a one-off, discrete shock associated with aging that mismatches workers with their jobs - mismatch shock (e.g., endurance decreases)
- Build a flexible empirical model of employment transitions to separate mismatch shock (Low, Meghir and Pistaferri, 2010; Altonji, Smith and Vidangos, 2013)
- Estimation: A modified stochastic EM algorithm studied in Wei (2021) for better algorithmic efficiency (Dempster, Laird and Rubin, 1977; Diebolt and Celeux, 1993; Liu, Rubin and Wu, 1998)

2. Conduct welfare analysis:

- Calculate the welfare cost of mismatch risk and how much people value the gradual transition to full retirement in a utility-based structural model (French, 2005; French and Jones, 2011; Berkovec and Stern, 1991; Jacobs and Piyapromdee, 2016)
- Policy-relevant: Heterogeneity across countries; Retirement age $\uparrow$
- Estimation: Develop a new simulation-based method that takes advantage of the estimated empirical model under the premise: The empirical model is more flexible than the structural model (Keane and Smith, 2003)

## The Empirical Model

For individual $i$ at period $t$, his employment, job, wages and working hours are determined

(1). Dynamic processes of shocks

- Health shock; Job destruction shock; General productivity shock; Job offer; Mismatch shock
(2). Employment and job transitions
- For the employed: stay employed or not? if stay employed, new job or not?
- For the non-employed: new job or not?
(3). Stochastic wage and hour equations
- Demographics, latent health, unobserved heterogeneity, general productivity, firm-worker-level job fit, tenure

## Mismatch Shock

- Mismatch shock: 0-1 discrete shock, capture non-marginal productivity decline associated to aging
- How does mismatch shock work in the model?

1. Affect the fit of the existing job fit: staying $\Rightarrow$ lower wages
2. Affect the outside offer (wages and hours): impaired skills might be required by other jobs too
3. Force job leave: capture other elements lead to job leave other than productivity reason

- Why mismatch shock might incentivise gradual transition (left-skewness in hour and wage changes)?

1. Worse outside offer
2. More likely to accept worse-paying offer: reservation wage changes

## Model Estimation by PX-SEM Algorithm

- Difficulty: latent components (e.g., health, productivity, fixed effect, mismatch)
- For latent-variable models, Stochastic EM (SEM) algorithm is a useful tool for estimation (Diebolt and Celeux, 1993).

Iterate between an E step and an M step until convergence to stationary distribution

- Problem: Inefficient in computing time $\rightarrow$ Infeasible to estimate complicated models
$\Rightarrow$ Explore a modified (parameter-expanded) stochastic EM algorithm (PX-SEM) to speed up convergence, studied in Wei (2021).

## Data

- The Health and Retirement Study (HRS) is a longitudinal panel study that surveys a representative sample of non-institutionalized individuals aged 50+ in US.
- Male individuals aged 51 to 70 in RAND HRS from 1996 to 2016 (11 waves)
- Never self-employed, and employed at least once during the sample periods
- Number of consecutive waves: $\geq 3$
- No missing data
- Sample size: $N=2,897, N \times T=15,277$

## Fit of Model

- Percentiles of log wage changes

## Results - How Much Risks Explain?

- Simulate without 1) mismatch, 2) job destruction, and 3) offer shocks

|  | $\Delta w$, movers, 61-70 |  |  |  | $\Delta h$, movers, 61-70 |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Mean | Var | $P 10$ | $P 90$ | Mean | Var | $P 10$ | $P 90$ |
| Baseline | -0.2 | 0.19 | -0.73 | 0.27 | -0.22 | 0.23 | -0.86 | 0.33 |
| No mismatch shocks | $58 \%$ | $72 \%$ | $77 \%$ | $104 \%$ | $29 \%$ | $36 \%$ | $51 \%$ | $92 \%$ |
| No jd shocks | $97 \%$ | $96 \%$ | $99 \%$ | $102 \%$ | $113 \%$ | $107 \%$ | $108 \%$ | $93 \%$ |
| No offer shocks | $75 \%$ | $51 \%$ | $79 \%$ | $61 \%$ | $76 \%$ | $59 \%$ | $77 \%$ | $87 \%$ |

Notes: In both panels, entries in the second row to the last display the ratios relative to the Baseline (first row).

## Quantifying The Welfare Costs- Structural Model Set-up

- Agents start life at 51 and live at most up to 90
- Goal: Maximize expected discounted lifetime utility (ink

1. Utility from consumption and leisure: $U\left(C_{t}, d_{t}\right)$
2. Utility from leaving a bequest: $b\left(A_{t}\right)$

- Choices: He receives a job offer each period and decide

1. Employment and job $d_{t}$
( 0 - nonemployed, 1 - stay in the existing job, 2 - work in a new job)
2. Consumption $\mathrm{C}_{t}$

- Risks: (ink

1. Mortality: $E\left(s_{t}\right)=f_{s}\left(h_{t-1}, t\right), s \in\{0,1\}$
2. Same risks as in the empirical model

- Welfare: government transfer, social security retirement benefits

## A New Simulation-based Method

- Connections between the empirical (E) and the structural (S) model:

1. $E$ and $S$ model share wage equation and latent variable dynamics
2. E employment \& job transitions can be seen as an approximate reduced form of the S model.
$\Rightarrow$ A new simulation-based estimation method that exploits E model results

- The estimator: choose S model that best approximates the estimated E model (Kullback-Leibler divergence)

$$
\hat{\Omega}=\arg \max _{\Omega} \sum \sum_{\widetilde{Z}} \ln f_{E}(Y, \widetilde{Z} ; \Theta(\Omega))
$$

where $\widetilde{Z} \sim f_{E}(Z \mid Y ; \hat{\Theta})$ : draws of latent variables $Z$ from posterior distribution given all observables $Y$ under E model estimates $\hat{\Theta}$

- Different from Indirect Inference: we use information on latent variables
- Allows us to bring the latent variable dynamics \& wage equation to $S$ model as primitive parameters

## What is The Welfare Cost of Mismatch Risk?

- Counterfactual: Eliminate mismatch risk by imposing $\operatorname{Prob}\left(m_{i t}=0\right)=1$
- Two welfare measures: measures

1. $\Delta A$ : the lump sum transfer of asset received at age 55/56
2. $\pi$ : the proportion of consumption per period after age 55/56

|  | $\Delta A(\times \$ 10,000)$ |  | $\pi$ |  |
| :---: | :---: | :---: | :---: | :---: |
|  | HE | LE | HE | LE |
| P10 | 3.98 | 1.45 | $5.9 \%$ | $4.34 \%$ |
| P50 | 6.23 | 2.67 | $7.11 \%$ | $5.33 \%$ |
| P90 | 8.62 | 4.57 | $7.99 \%$ | $6.18 \%$ |

## What is The Welfare Cost of Inflexible Transitions?

- Counterfactual: Ban the job change and re-entry for people older than 65
- Two welfare measures: measures

1. $\Delta A$ : the lump sum transfer of asset received at age $55 / 56$
2. $\pi$ : the proportion of consumption per period after age $55 / 56$

|  | $\Delta A(\times \$ 10,000)$ |  | $\pi$ |  |
| :---: | :---: | :---: | :---: | :---: |
|  | HE | LE | HE | LE |
| p 10 | -17.4 | -13.4 | $-13.78 \%$ | $-16.79 \%$ |
| p 50 | -10.73 | -5.84 | $-12.65 \%$ | $-13.53 \%$ |
| p 90 | -5.55 | -2.98 | $-10.88 \%$ | $-10.52 \%$ |

## Conclusion

- I study the risks and gradual transition to full retirement of older workers
- Empirical contribution: Propose an aging-related mismatch shock which could explain the job movements to worse-paying and less-demanding jobs
- Methodological contribution: Develop a new simulation-based estimation algorithm to combine empirical model (risks) and the structural model (welfare calculation)
- I find that
- Mismatch shock can explain the job movements to worse-paying, less-demanding jobs
- Mismatch risk causes non-negligible amount of welfare loss
- People value the possibility of a smooth transition to retirement

## Appendix - (1) Dynamic Processes: Health

Latent health:

$$
\begin{equation*}
h_{i t}=f_{h}\left(h_{i, t-1}, a g e_{i, t-1}, \varepsilon_{i t}^{h}\right) \tag{1}
\end{equation*}
$$

Measurement equation:

$$
\begin{equation*}
s r h_{i t}=\sum_{k=1}^{5} 1\left(h_{i t}>\tau_{k}^{s h}\right) \tag{2}
\end{equation*}
$$

- $h_{i t}$ is an underlying continuous index not observed by researchers
- The self-reported health $s r h_{i t}$, containing information of $h_{i t}$, is observed
- The value of $s r h_{i t}$ : discrete, varying from 1 (Excellent) to 5 (Poor)

## Appendix - (1) Dynamic Processes: Individual-specific Productivity

Productivity $\omega_{i t}$ and productivity risk $\sigma_{i t}$

$$
\begin{align*}
& \omega_{i t}=\rho\left(\sigma_{i t}, a g e_{i, t-1}\right) \omega_{i, t-1}+\varepsilon_{i t}^{\omega} \sigma_{i t}  \tag{3}\\
& \sigma_{i t}=f_{\sigma}\left(e d u_{i}, a g e_{i, t-1}, h_{i, t-1}, \sigma_{i, t-1}, \varepsilon_{i t}^{\sigma}\right) \tag{4}
\end{align*}
$$

- Heterogeneity in productivity risks and depreciation of productivity
- Non-linear persistence in income dynamics: e.g., negative health history causes non-marginal drop in productivity.

## Appendix - (1) Dynamic Processes: Job Destruction

Job destruction shock

$$
\begin{equation*}
j d_{i t}=1\left\{f_{j d}\left(e d u_{i}\right)+\varepsilon_{i t}^{j d}>0\right\} \tag{5}
\end{equation*}
$$

- Only triggers a job leave
- No impact on productivity and offer

## Appendix - (1) Dynamic Processes: The Existing Job

Dynamics of $\left(v_{i j t}, \xi_{i j t}\right)$ :

$$
\begin{gather*}
\left\{\begin{aligned}
v_{i j t} & =v_{i, t-1}, \text { if } m_{i j t}=0 \\
v_{i j t} & \ll v_{i, t-1}, \text { if } m_{i j t}=1
\end{aligned}\right.  \tag{6}\\
\xi_{i j t}=\xi_{i, t-1} \tag{7}
\end{gather*}
$$

- Hour component stays constant during a job tenure
- When mismatch happens, wage to be received from the existing job is reduced to a much smaller value that triggers a job leave

## Appendix - (1) Dynamic Processes: The New Job

Dynamics of $\left(v_{i j^{\prime} t}, \xi_{i j^{\prime} t}\right)$ :

$$
\begin{align*}
v_{i j^{\prime} t} & =f_{v}\left(v_{i j t}, E_{i, t-1}, e d u_{i}\right)+\varepsilon_{i t}^{v}  \tag{8}\\
\xi_{i j^{\prime} t} & =f_{\xi}\left(\xi_{i j t}, E_{i, t-1}, e d u_{i}, v_{i j^{\prime} t}\right)+\varepsilon_{i t}^{\xi} \tag{9}
\end{align*}
$$

- When mismatch happens, offer is also affected through terms $v_{i j t}$ and $\xi_{i j t}$
- The wages of the mismatched are expected to be lower on average
- Worse outside offer
- More likely to accept worse-paying offer: either the offer or non-employment

## Appendix - Older Workers In HRS

- There is a non-negligible number of employment and job movements, and the movements do not concentrate on a narrow age group.

|  | Age group |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
|  | All | $\leq 55$ | $55 \sim 60$ | $60 \sim 65$ | $>65$ |
| Individual |  |  |  |  |  |
| People who have started new jobs | 0.32 | 0.16 | 0.21 | 0.17 | 0.13 |
| $\quad$ job-to-job transition | 0.21 | 0.12 | 0.15 | 0.10 | 0.05 |
| re-entry | 0.14 | 0.03 | 0.06 | 0.06 | 0.08 |
| Individual-year |  |  |  |  |  |
| Employment to Employment | 0.60 | 0.87 | 0.78 | 0.54 | 0.30 |
| Employment to Nonemployment | 0.14 | 0.08 | 0.10 | 0.18 | 0.14 |
| Nonemployment to Employment | 0.04 | 0.03 | 0.04 | 0.03 | 0.04 |

## Appendix — Older Workers In HRS

- There is heterogeneity between stayers and movers
- The wage and hour changes among movers are more dispersive
- The wage and hour changes of movers are more left-skewed

(a) Log wage changes

(b) Log hour changes

## Appendix — Older Workers In HRS

- There is heterogeneity between stayers and movers
- The wage and hour changes among movers are more dispersive
- The wage and hour changes of movers are more left-skewed

(a) Log wage changes, Tenure $\geq 10 \mathrm{yrs}$

(b) Log hour changes, Tenure $\geq 10 \mathrm{yrs}$

## Appendix - Model Specification

## back

Dynamics of Assets:

$$
\begin{equation*}
E\left(1\left(A_{i t}<\tau_{k}^{A}\right)\right)=\Phi\left(f_{A, k}\left(X_{i t}, A_{i, t-1}, E_{i t}, w_{i t}^{*}, l_{i t}, h_{i t}, \omega_{i t}, v_{i t}, \mu_{i}\right)\right) \tag{10}
\end{equation*}
$$

Empirical model assumptions:

- i.i.d. all error terms
- Normal distributions

## Appendix — Mismatch Shocks

- How likely for workers to receive mismatch shocks?
- Per individual-period:

|  | $51 \sim 55$ | $56 \sim 60$ | $61 \sim 65$ | $66 \sim 70$ |
| :--- | :---: | :---: | :---: | :---: |
| HE | $0.8 \%$ | $2.5 \%$ | $4.4 \%$ | $4.2 \%$ |
| LE | $0.4 \%$ | $1.4 \%$ | $2.7 \%$ | $3.1 \%$ |

- Per individual: Probability of receiving at least one mismatch shock by age 65 and 70 are $10.3 \%$ and $13.5 \%$, respectively.
- Among movers who switch to worse-paying jobs, how many received mismatch shocks?

| $\Delta w_{t} \leq$ | $51 \sim 55$ | $56 \sim 60$ | $61 \sim 65$ | $66 \sim 70$ |
| :---: | :---: | :---: | :---: | :---: |
| -0.1 | $9.8 \%$ | $30.8 \%$ | $56.4 \%$ | $63.2 \%$ |
| -0.3 | $13.5 \%$ | $40.2 \%$ | $64.8 \%$ | $69.9 \%$ |

## Results — Bridge Job

- In this exercise, I label any jobs after a job with $\geq 10 y r s$ of tenure as a "bridge job"

|  | Bridge job (IDVI.) | $E(\Delta w)$ | $\operatorname{Var}(\Delta w)$ | $E(\Delta h)$ | $\operatorname{Var}(\Delta h)$ |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Model | 0.13 | -0.49 | 0.25 | -0.31 | 0.33 |
| No mismatch shocks | $88 \%$ | $78 \%$ | $66 \%$ | $32 \%$ | $35 \%$ |
| No jd shocks | $89 \%$ | $99 \%$ | $103 \%$ | $109 \%$ | $104 \%$ |
| No offer shocks | $91 \%$ | $123 \%$ | $56 \%$ | $107 \%$ | $54 \%$ |

Notes: Entries in the second row to the last display the ratios relative
to the Baseline (first row). Columns 2-5 computed for the first bridge job.

## Appendix - Bridge Jobs

- Bridge jobs: those connect career employment with the full retirement
- In this exercises: define career employment as any job with $\geq 10 y r s$ of tenure

Table: Job, mean and variance of wage change conditional on tenure larger than 10yrs

|  | Proportion of IDVI |  |  | $E(\Delta w)$ |  |  | $\operatorname{Var}(\Delta w)$ |  |  | $E(\Delta h)$ |  |  | $\operatorname{Var}(\Delta h)$ |  |  |

## Appendix - Empirical Model Implications

Figure: Wage Persistence

## Appendix — U Model Utility

Utility from consumption and leisure: back

$$
U\left(C_{t}, d_{t}, d_{t-1}, j d_{t}, h_{t}, \epsilon_{t}^{d}\right)=\frac{1}{1-v} C_{t}^{1-v}+L_{t}
$$

where

$$
\begin{aligned}
L_{t}= & -\left(\theta_{e 0}+\theta_{e 1} t+\theta_{e 2} 1(t>6)(t-6)+\theta_{e 3} h_{t}\right) E_{t} \\
& -\left(\theta_{r 0}+\theta_{r 1} t+\theta_{r 2} 1(t>6)(t-6)+\theta_{r 3} h_{t}\right) R E_{t} \\
& -\left(\theta_{j 0}+\theta_{j 1} t+\theta_{j 2} 1(t>6)(t-6)+\theta_{j 3} h_{t}\right) J C_{t}+\epsilon_{t}^{d}
\end{aligned}
$$

- $E_{t}:$ Being employed, $E_{t}=1\left\{d_{t}=1\right.$ or $\left.d_{t}=2\right\}$
- $R E_{t}$ : Re-entry (NE-E movement), $R E_{t}=1\left\{E_{1}=1\right.$, $\operatorname{and}\left(E_{t-1}=0\right)$ or $j d_{t}=1$ or $\left.\left.m_{t}=1\right)\right\}$
- $J C_{t}$ : Job changes (JC movement), $J C=1\left\{E_{t-1}=1, j d_{t}=0, m_{t}=0, E_{t}=1\right\}$
- $\epsilon_{t}^{d}$ : idiosyncratic preference shocks, i.i.d. Type-I extreme Value distribution

Utility from leaving a bequest for people who die at period $t$ :

$$
b\left(A_{t}\right)=\kappa A_{t} 1\left(A_{t} \geq 0\right)
$$

## Appendix — U Model Risks

back

Risks:

- Survival: $E\left(s_{t}\right)=f_{s}\left(h_{t-1}, t\right), s \in\{0,1\}$
- Composite firm-specific component and offers:

$$
\begin{aligned}
& \widetilde{v}_{j(t)}= \begin{cases}\rho_{v 0}+\rho_{v} \widetilde{v}_{j(t-1)} & \text { if stay at the same job } \\
\widetilde{v}_{j(t)}^{\prime} & \text { if move to new job }\end{cases} \\
& \widetilde{v}_{j(t)}^{\prime} \sim f_{v^{\prime}}\left(\widetilde{v}_{j, t-1}, m_{j t}, j d_{i t}, E_{t-1}\right)
\end{aligned}
$$

- Mismatch: $E\left(m_{j t}\right)=f_{m}\left(t, e d u, \widetilde{v}_{t-1}, E_{t-1}\right), m_{j t} \in\{0,1\}$
- Job destruction: $E\left(j d_{t}\right)=f_{j d}\left(t, e d u, \tilde{v}_{t-1}, m_{j t}\right)$
- Other components, including health $h_{t}$, individual-specific wage component $\omega_{t}$, and the productivity risks $\sigma_{t}$ are the same as in the empirical model

## Appendix— U Model Budget Constraint

## back

Budget constraint:

$$
A_{t+1}=(1+r) A_{t}+Y_{t}+s s_{t} \times B_{t}+t r_{t}-C_{t}
$$

- Labor income: $Y_{t}=W_{t} \times N$,
in which the log hourly wage rate:

$$
\ln W_{t}=X_{t}^{\prime} \gamma_{X}+h_{t} \gamma_{h}+\omega_{t}+\widetilde{v}_{t}
$$

- Exclude measurement errors from the wage equation.
- Reduce the dimensionality of state variables:
* Fixed hour supply $N$
* Define a a composite firm component $\widetilde{v} \equiv \mu+t e n_{t}^{\prime} \gamma_{\text {ten }}^{z v}+v$
- Borrowing constraint: $A_{t+1} \geq A_{\text {min }}$,
- Government transfers $t r_{t}$ : guarantees a minimum consumption $C_{\min }$
- Social security income $s s_{t}$ : everyone collects social security after 65: $B_{t}=1\{t \geq 8\}$, with a fixed

## Appendix - Optimzation Problem

back
Value function:

$$
\begin{aligned}
V_{t}\left(\Omega_{t}\right)= & \max _{C_{t}, d_{t}}\left\{U\left(C_{t}, d_{t}, d_{t-1}, j d_{t}, h_{t}, \epsilon_{t}^{d}\right)+\beta\left(1-s_{t+1}\right) b\left(A_{t+1}\right)\right. \\
& \left.+\beta s_{t+1} E\left(V_{t+1}\left(\Omega_{t+1}\right) \mid \Omega_{t}, C_{t}, d_{t}\right)\right\} \\
\text { s.t. } & A_{t+1}=(1+r) A_{t}+Y_{t}+s s_{t} \times B_{t}+t r_{t}-C_{t} \\
& A_{t+1} \geq A_{\text {min }}, C_{t} \geq C_{\text {min }}
\end{aligned}
$$

with state variables $\Omega_{t}=\left(A_{t-1}, \tilde{v}_{t-1}, \widetilde{v}_{t}^{\prime}, \omega_{t}, \sigma_{t}, h_{t}, m_{t}, t, d_{t-1}, j d_{t}, e d u, \epsilon_{t}^{d}\right)$

## Appendix - Structural Model Solution

back

- Model Solution
- Backward induction
- Discretization
- Grouping individuals by age: $51 \sim 52,53 \sim 54, \ldots 89 \sim 90$
- Type-I extreme value assumption of preference shocks

## Appendix - Structural Model Solution

back

- Steps:

1. Primitive parameters $\hat{\Omega}_{1}$ : survival probability; approximation due to $\widetilde{v}$.
2. Remaining parameters $\Omega_{2}$ are estimated:

$$
\hat{\Omega}_{2}=\arg \max _{\Omega_{2}} \sum \sum_{\widetilde{Z}} \ln f_{N U}\left(Y, \widetilde{Z} ; \Theta\left(\Omega_{2}, \hat{\Omega}_{1}\right)\right)
$$

- Details on step 2:
- Start with an initial guess of $\Omega_{2}$. Given $\hat{\Omega}_{1}$ and $\Omega_{2}$, simulate $M$ statistically independent data sets from the $U$ model: $\{Y, Z\}^{m}, m=1, \ldots, M$, where each data set consists of $N_{M}$ individuals and $T_{M}$ periods.
- Then compute $\Theta\left(\Omega_{2}, \hat{\Omega}_{1}\right)=\frac{1}{M} \Sigma \hat{\Theta}^{m}\left(\Omega_{2}, \hat{\Omega}_{1}\right)$, where $\hat{\Theta}^{m}$ is the estimator for each of the $M$ simulated data sets: $\hat{\Theta}^{m}\left(\Omega_{2}, \hat{\Omega}_{1}\right)=\arg \max _{\Theta} \ln f_{N U}\left(Y^{m}, Z^{m} ; \Theta\right)$.
- Evaluate the objective function $\Sigma \Sigma_{\widetilde{Z}} \ln f_{N U}\left(Y, \widetilde{Z} ; \Theta\left(\Omega_{2}, \hat{\Omega}_{1}\right)\right)$ (only ee, ne, jc, $\left.A_{t}\right)$.

Choose $\Omega_{2}$ that maximizes the objective function ( $M=50, N_{M}=10,000, T_{M}=6$ ).

## Appendix - Structural Model Estimates

|  | Parameters | HE | LE |  | Parameters | HE | LE |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## Appendix - Fit of structural model

Figure: Asset Accumulation

## Appendix - Welfare Measures

back

- Measure of welfare gain or loss:
- Lump sum transfer of asset $\Delta A$, at age $55 / 56$, ( $\mathrm{t}=3$ )

$$
V_{3}\left(A_{2}+\Delta A, \Omega_{3} \backslash A_{2}\right)=\widetilde{V}_{3}\left(\Omega_{3}\right)
$$

- Proportion of consumption adjusted, $\pi$, in all ages since $55 / 56(t \geq 3)$

$$
V_{3}\left(\Omega_{3}\right)+\sum_{t=3} \beta^{t-3} E_{3}\left(s(t) \frac{1}{1-v}\left(\pi C_{t}^{*}\right)^{1-v}\right)=\widetilde{V}_{3}\left(\Omega_{3}\right)
$$

## Appendix - What is The Welfare Cost of Mismatch Risk?
