Motivation

- ▶ Macro finance models involve aggregate risk + multiple assets
- ▶ Those models are challenging to solve
- ▶ Classical solution methods often fail, because
 - ▶ Multiple assets quickly make the state space high-dimensional
 - ▶ Grid based methods don't scale
 - ▶ Linearization kills risk premia
 - ▶ Higher-order perturbations require too much smoothness

Starting point

- ▶ Deep learning based solution methods: Azinovic et al. (2022) (**DEQN**), Ebrahimi Kahou et al. (2021); Maliar et al. (2021); Kase et al. (2022); Gu et al. (2023).¹
 - ▶ Deep neural networks as an approximator for equilibrium functions of the economy
 - ▶ Trained to minimize equilibrium conditions error on a simulated ergodic set
- ▶ DEQN can handle stochastic models with many state variables, however, two pain points remain:
 - ▶ Portfolio choice
 - ▶ Market clearing

¹See also Han et al. (2021); Valaitis and Villa (2021); Fernández-Villaverde et al. (2023), for different approaches involving deep learning.

This paper

- ▶ Two complementary innovations
 1. Market clearing layers
 2. Adiabatic model transformations for portfolio choice and asset prices
- ▶ Market clearing layers: neural network predictions are consistent with market clearing by design
- ▶ Adiabatic model tranformations: smoothly solve models with multiple assets

DEQN

Violations of equilibrium conditions as loss function

Basic idea in Azinovic et al. (2022): write equilibrium conditions as

$$\mathbf{G}(\mathbf{x}, \mathbf{f}) = 0 \quad \forall \mathbf{x}$$

\mathbf{G} : equilibrium conditions: FOC's, market clearing, Bellman equations, ...

\mathbf{x} : state of the economy

\mathbf{f} : equilibrium functions.

Approximate equilibrium functions by neural network $\mathcal{N}_\rho(\cdot)$ Neural Nets

$$\mathcal{N}_\rho(\mathbf{x}) \approx \mathbf{f}(\mathbf{x})$$

Given network parameters ρ , we define a **loss function**

$$l_\rho := \frac{1}{N_{\text{path length}}} \sum_{\mathbf{x}_i \text{ on sim. path}} (\mathbf{G}(\mathbf{x}_i, \mathcal{N}_\rho))^2$$

If $l_\rho \approx 0$, then $\mathcal{N}_\rho(\mathbf{x})$ gives us a good approximation of $\mathbf{f}(\mathbf{x})$.

Training DEQNs

1. Simulate a sequence of states $\mathcal{D}_{\text{train}}^i \leftarrow \{\mathbf{x}_1^i, \mathbf{x}_2^i, \dots, \mathbf{x}_T^i\}$ from the policy encoded by the network parameters ρ^i .
2. Evaluate the errors of the equilibrium conditions on the newly generated set $\mathcal{D}_{\text{train}}$.
3. If the error statistics are not low enough:
 - 3.1 Update the parameters of the neural network with a gradient descent step (or a variant):

$$\rho_k^{i+1} = \rho_k^i - \alpha_{\text{learn}} \frac{\partial \ell_{\mathcal{D}_{\text{train}}^i}(\rho^i)}{\partial \rho_k^i}.$$

- 3.2 Set new starting states for simulation: $\mathbf{x}_0^{i+1} = \mathbf{x}_T^i$.
- 3.3 Increase i by one and go back to step 1.

Simple Model

Simple OLG model with Capital and Bond

- Representative firm produces with

$$F(z_t, K_t, L_t) = z_t K_t^\alpha L_t^{1-\alpha} \quad (1)$$

$$w_t = \alpha z_t K_t^{\alpha-1} L_t^{1-\alpha} \quad (2)$$

$$r_t = z_t(1 - \alpha) K_t^\alpha L_t^\alpha. \quad (3)$$

- Uncertainty in TFP z_t , and depreciation of capital δ_t

$$\log(z_{t+1}) = \rho_z \log(z_t) + \sigma_z \epsilon_t \quad (4)$$

$$\epsilon_t \sim N(0, 1) \quad (5)$$

$$\delta_t = \delta \frac{2}{1+z} \quad (6)$$

- Assets

- One period bond with price p_t in aggregate supply B
- Risky capital K_t
- Borrowing constraints on both assets

$$b_t^h \geq 0 \quad (7)$$

$$k_t^h \geq 0 \quad (8)$$

- Households

- $H = 32$ age-groups, indexed with $h \in \mathcal{H} := \{1, \dots, 32\}$
- supply labor units l_t^h inelastically
- adjustment costs on capital

$$\Delta_{k,t}^h := k_{t+1}^{h+1} - k_t^h \quad (9)$$

$$\text{adj. costs} = \psi (\Delta_{k,t}^h)^2 \quad (10)$$

- budget constraint

$$c_t^h = l_t^h w_t + b_{t-1}^{h-1} + k_{t-1}^{h-1} (1 - \delta_t + r_t) - p_t^b b_t^h + k_t^h - \psi (\Delta_{k,t}^h)^2 \quad (11)$$

- Maximize

$$\mathbb{E} \left[\sum_{i=h}^H \beta^{i-h} u(c_{t+i}^{h+i}) \right] \quad (12)$$

$$u(c) := \frac{c^{1-\gamma} - 1}{1 - \gamma} \quad (13)$$

Equilibrium conditions

- Market clearing:

$$K_t := \sum_{h \in \mathcal{H}} k_t^h \quad (14)$$

$$B = \sum_{h \in \mathcal{H}} b_t^h \Leftrightarrow \epsilon_t^B := B - \sum_{h \in \mathcal{H}} b_t^h = 0 \quad (15)$$

- Firms optimize:

$$\begin{aligned} w_t &:= \alpha z_t K_t^{\alpha-1} L_t^{1-\alpha} \\ r_t &:= z_t(1-\alpha) K_t^\alpha L_t^\alpha \end{aligned}$$

- Households optimize:

$$\left. \begin{array}{l} 1 = \frac{\beta \mathbb{E} [u'(c_{t+1}^{h+1})(1-\delta_{t+1}+r_{t+1}+2\psi^k \Delta_{k,t+1}^{h+1}) + \mu_t^h]}{(1+2\psi^k \Delta_{k,t}^h) u'(c_t^h)} \\ k_t^h \geq 0 \\ \mu_t^h \geq 0 \\ k_t^h \mu_t^h = 0 \end{array} \right\} \Leftrightarrow \epsilon_t^{k,h} := \psi^{FB} \left(\frac{u'^{-1} \left(\beta \mathbb{E} \left[u'(c_{t+1}^{h+1}) \frac{(1-\delta_{t+1}+r_{t+1}+2\psi^k \Delta_{k,t+1}^{h+1})}{(1+2\psi^k \Delta_{k,t}^h)} \right] \right)}{c_t^h} - 1, \frac{k_t^h}{c_t^h} \right) = 0$$

$$\left. \begin{array}{l} 1 = \frac{\beta \mathbb{E} [u'(c_{t+1}^{h+1})] + \lambda_t^h}{\rho_t^b u'(c_t^h)} \\ b_t^h - \underline{b} \geq 0 \\ \lambda_t^h \geq 0 \\ (b_t^h - \underline{b}) \lambda_t^h = 0 \end{array} \right\} \Leftrightarrow \epsilon_t^{b,h} := \psi^{FB} \left(\frac{u'^{-1} \left(\beta \mathbb{E} \left[\frac{1}{\rho_t^b} u'(c_{t+1}^{h+1}) \right] \right)}{c_t^h} - 1, \frac{b_t^h - \underline{b}}{c_t^h} \right) = 0$$

where

$$\psi^{FB}(a, b) := a + b - \sqrt{a^2 + b^2} \quad (16)$$

Approximation with standard DEQN

- State of the economy

$$\mathbf{x}_t = [\underbrace{z_t}_{\text{ex. shock}}, \underbrace{k_t^1, \dots, k_t^{32}}_{\text{dist. of cap.}}, \underbrace{b_t^1, \dots, b_t^{32}}_{\text{dist. of bonds}}] \quad (17)$$

- Equilibrium policies

$$\mathbf{f}(\mathbf{x}_t) = [\underbrace{k_{t+1}^1, \dots, k_{t+1}^{32}}_{\text{capital policy}}, \underbrace{b_{t+1}^1, \dots, b_{t+1}^{32}}_{\text{bond policy}}, \underbrace{p_t^b}_{\text{bond price}}] \quad (18)$$

- Neural network approximates

$$\mathcal{N}_\rho(\mathbf{x}_t) = [\underbrace{\hat{k}_{t+1}^1, \dots, \hat{k}_{t+1}^{32}}_{\text{capital policy}}, \underbrace{\hat{b}_{t+1}^1, \dots, \hat{b}_{t+1}^{32}}_{\text{bond policy}}, \underbrace{\hat{p}_t^b}_{\text{bond price}}] \approx \mathbf{f}(\mathbf{x}_t) \quad (19)$$

- loss function

$$\ell_\rho(\mathbf{x}_t) := \underbrace{w_{hh,k}}_{\text{weight}} \underbrace{\left(\sum_{h=1}^{H-1} (\epsilon_t^{k,h})^2 \right)}_{\text{opt. cond. cap.}} + \underbrace{w_{hh,b}}_{\text{weight}} \underbrace{\left(\sum_{h=1}^{H-1} (\epsilon_t^{b,h})^2 \right)}_{\text{opt. cond. bond}} + \underbrace{w_{mc,B}}_{\text{weight}} \underbrace{(\epsilon_t^B)^2}_{\text{market clearing}} \quad (20)$$

Motivation for market clearing layers

- ▶ Loss function should encode all equations which pin-down equilibrium objects of the economy
 - ▶ First-order conditions
 - ▶ Bellman equations
 - ▶ Market clearing
 - ▶ Government budget constraint
- ▶ Problem: different equations have **different units** or different **economic relevance**
- ▶ More terms in loss function ⇒ **harder to interpret** the resulting loss
- ▶ Simulated states are **not consistent** with the equilibrium conditions
- ▶ **Why force the neural network to learn something we already know?**

Innovation 1: Market clearing layers

- Neural network first predicts

$$\mathcal{N}_\rho^{\text{pre}}(\mathbf{x}_t) = [\hat{k}_{t+1}^1, \dots, \hat{k}_{t+1}^{32}, \tilde{b}_{t+1}^1, \dots, \tilde{b}_{t+1}^{32}, \hat{p}_t^b] \quad (21)$$

- Apply transformation $m(\dots, \cdot)$

$$[\hat{b}_{t+1}^1, \dots, \hat{b}_{t+1}^{32}] = m(\mathcal{N}_\rho^{\text{pre}}(\mathbf{x}_t), B) \quad (22)$$

- Such that

$$B = \sum_{h=1}^{32} \hat{b}_{t+1}^h \quad (23)$$

- Put together

$$\mathcal{N}_\rho(\mathbf{x}_t) := [\hat{k}_{t+1}^1, \dots, \hat{k}_{t+1}^{32}, \hat{b}_{t+1}^1, \dots, \hat{b}_{t+1}^{32}, \hat{p}_t^b] \quad (24)$$

- Loss function now

$$\ell_\rho(\mathbf{x}_t) := \underbrace{w_{hh,k}}_{\text{weight}} \underbrace{\left(\sum_{h=1}^{H-1} (\epsilon_t^{k,h})^2 \right)}_{\text{opt. cond. cap.}} + \underbrace{w_{hh,b}}_{\text{weight}} \underbrace{\left(\sum_{h=1}^{H-1} (\epsilon_t^{b,h})^2 \right)}_{\text{opt. cond. bond}} + \underbrace{w_{mc,B}}_{\text{weight}} \underbrace{(\epsilon_t^B)^2}_{\text{market clearing}} = 0 \quad (25)$$

1. remaining loss easier to interpret
2. states simulated from the policy are always consistent with market clearing

Innovation 1: Details on the market clearing transformation function

- ▶ Simple market clearing layer: subtract excess demand ED_t from initial predictions

$$ED_t := \sum_{h \in \mathcal{H}} \tilde{b}_{t+1}^h - B \quad (26)$$

$$\hat{b}_{t+1}^h := \tilde{b}_{t+1}^h - \frac{1}{H} ED_t \quad (27)$$

- ▶ Why this adjustment?

→ we try to minimize the modification to the initial predictions $\{\tilde{b}_{t+1}^h\}_{h \in \mathcal{H}}$.

- ▶ Final predictions $\{\hat{b}_{t+1}^h\}_{h \in \mathcal{H}}$ solve

$$\arg \min_{\{x_{t+1}^h\}_{h \in \mathcal{H}}} \sum_{h \in \mathcal{H}} \left(x_{t+1}^h - \hat{b}_{t+1}^h \right)^2 \quad (28)$$

subject to

$$\sum_{h \in \mathcal{H}} x_{t+1}^h = B \quad (29)$$

Innovation 1: Details on the market clearing transformation function

- ▶ Simple market clearing layer: subtract excess demand ED_t from initial predictions

$$ED_t := \sum_{h \in \mathcal{H}} \tilde{b}_{t+1}^h - B \quad (26)$$

$$\hat{b}_{t+1}^h := \tilde{b}_{t+1}^h - \frac{1}{H} ED_t \quad (27)$$

- ▶ Why this adjustment?

→ we try to minimize the modification to the initial predictions $\{\tilde{b}_{t+1}^h\}_{h \in \mathcal{H}}$.

- ▶ Final predictions $\{\hat{b}_{t+1}^h\}_{h \in \mathcal{H}}$ solve

$$\arg \min_{\{x_{t+1}^h\}_{h \in \mathcal{H}}} \sum_{h \in \mathcal{H}} (x_{t+1}^h - \hat{b}_{t+1}^h)^2 \quad (28)$$

subject to

$$\sum_{h \in \mathcal{H}} x_{t+1}^h = B \quad (29)$$

- ▶ Downside: borrowing constraint not necessarily satisfied.
- ▶ In the paper: enforcing market clearing & borrowing constraints using **implicit layer**
- ▶ Downside: slows down the algorithm, need to restore signal for falsely constrained agents

Innovation 2: Stabilizing adiabatic model transformations

- ▶ Single asset models are easy
- ▶ Many asset models are hard
- ▶ Why?
 - ▶ Portfolio choice only pinned down at low errors in equilibrium conditions
 - ▶ But how do we get there?

▶ Adiabatic model transformations

1. $N - 1$ asset models are nested in N asset models
2. Start with single asset model

$$\mathcal{N}_\rho^1(\mathbf{x}_t) = [\hat{k}_{t+1}^1, \dots, \hat{k}_{t+1}^{32}, \mathbf{0} \times \hat{b}_{t+1}^1, \dots, \mathbf{0} \times \hat{b}_{t+1}^{32}, \hat{p}_t^b], B^1 = 0 \quad (30)$$

3. Solve the model
4. Train bond price (**supervised, from zero liquidity limit**)
5. Slowly introduce the second asset

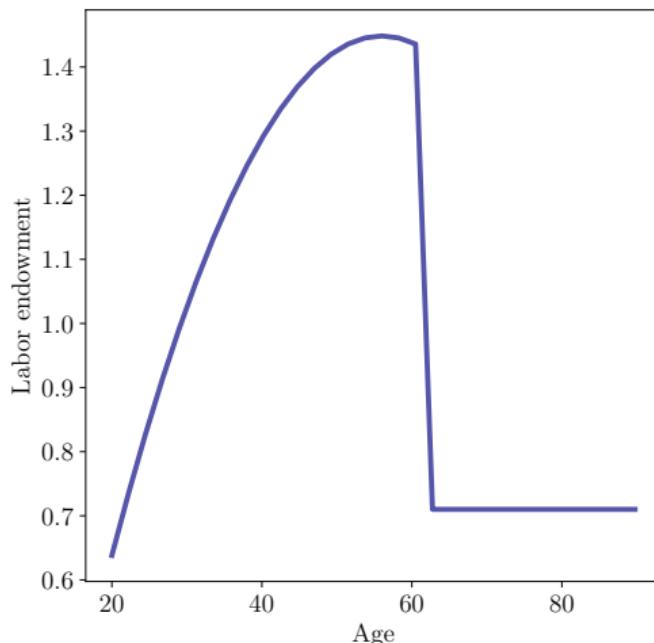

$$\mathcal{N}_\rho^{\dots}(\mathbf{x}_t) = [\hat{k}_{t+1}^1, \dots, \hat{k}_{t+1}^{32}, \mathbf{1} \times \hat{b}_{t+1}^1, \dots, \mathbf{1} \times \hat{b}_{t+1}^{32}, \hat{p}_t^b], B^{\dots} = \dots$$

6. Equilibrium errors **always remain low**

Application to our simple model

Parameters

Parameters	H	β	γ	ψ	ρ	σ	α
Values	32	0.912	4	0.1	0.693	0.052	0.333
Meaning	num. age groups	patience	RRA	adj. costs	pers. tfp	std. innov. tfp	cap. share

Step 1: solve single asset model

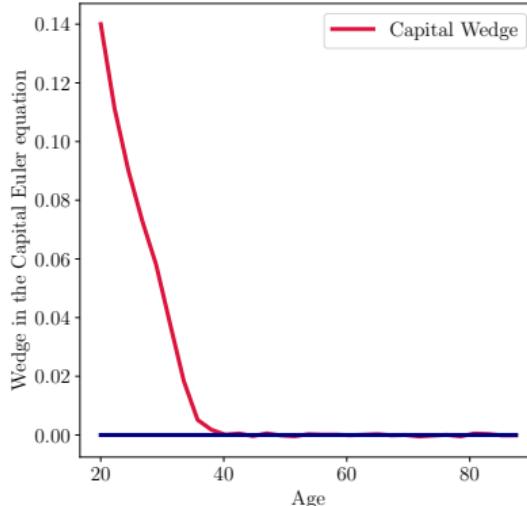

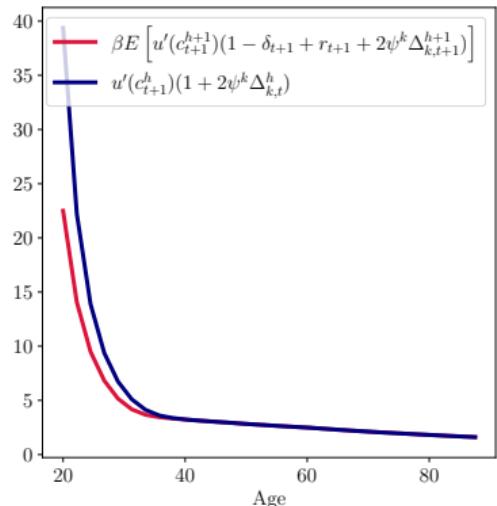

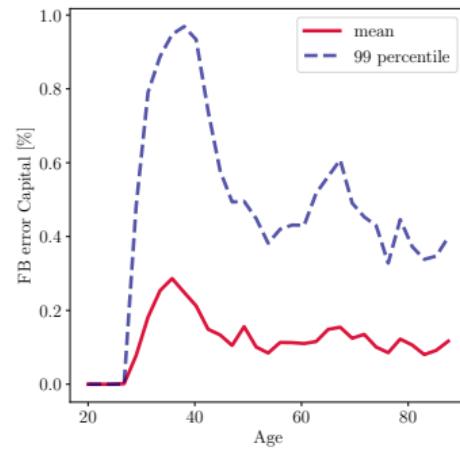

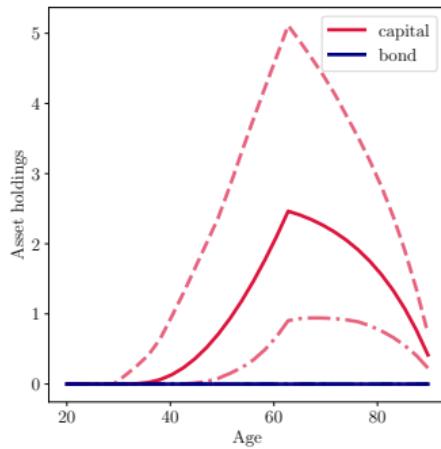

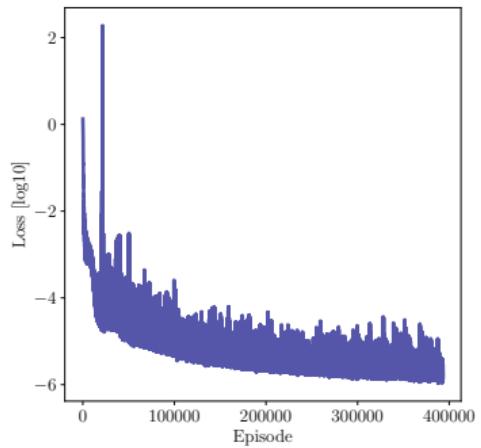

- ▶ Borrowing constraint $\underline{b} = 0$, net-supply $B = 0$
- ▶ Neural network predicts

$$\mathcal{N}_\rho^{\text{pre}}(\mathbf{x}_t) = [\hat{k}_{t+1}^1, \dots, \hat{k}_{t+1}^{32}, \color{red}{0 \times} \tilde{b}_{t+1}^1, \dots, \color{red}{0 \times} \tilde{b}_{t+1}^{32}, \hat{p}_t^b] \quad (31)$$

$$\Rightarrow \mathcal{N}_\rho(\mathbf{x}_t) = [\hat{k}_{t+1}^1, \dots, \hat{k}_{t+1}^{32}, \color{red}{0}, \dots, \color{red}{0}, \hat{p}_t^b] \quad (32)$$

- ▶ Loss function

$$\ell_\rho(\mathbf{x}_t) := \underbrace{\color{red}{1 \times} \left(\sum_{h=1}^{H-1} (\epsilon_t^{k,h})^2 \right)}_{\text{opt. cond. cap.}} + \underbrace{\color{red}{0 \times} \left(\sum_{h=1}^{H-1} (\epsilon_t^{b,h})^2 \right)}_{\text{opt. cond. bond}} \underbrace{= 0}_{\color{red}=0} \quad (33)$$

Step 2: pretrain bond price in the capital only model

- Keep borrowing constraint $\underline{b} = 0$, net-supply $B = 0$, and neural network masks

$$\mathcal{N}_\rho(\mathbf{x}_t) = [\hat{k}_{t+1}^1, \dots, \hat{k}_{t+1}^{32}, \mathbf{0}, \dots, \mathbf{0}, \hat{p}_t^b] \quad (34)$$

- In equilibrium we know that

$$p_t^b \geq \frac{\beta E[u'(c_{t+1}^{h+1})]}{u'(c_t^h)} \quad (35)$$

with equality for unconstrained agents.

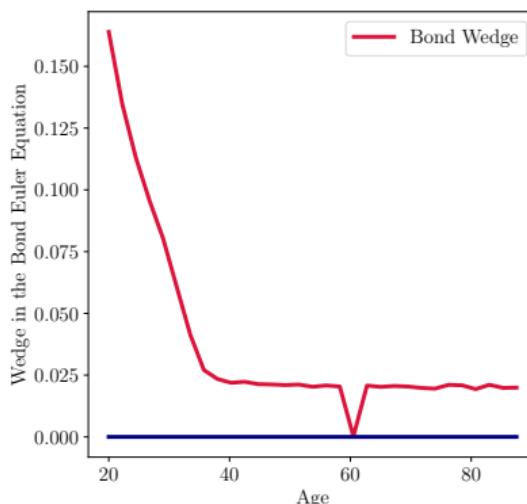

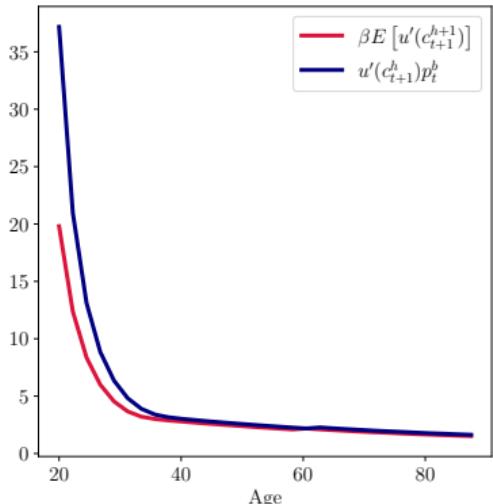

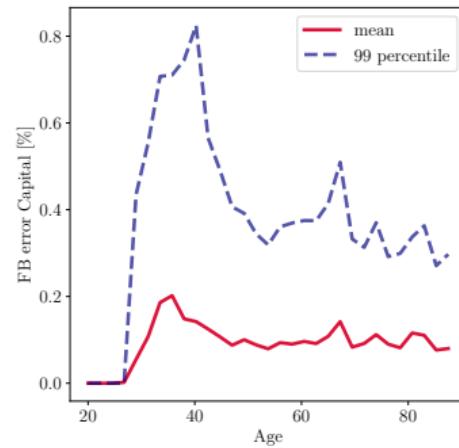

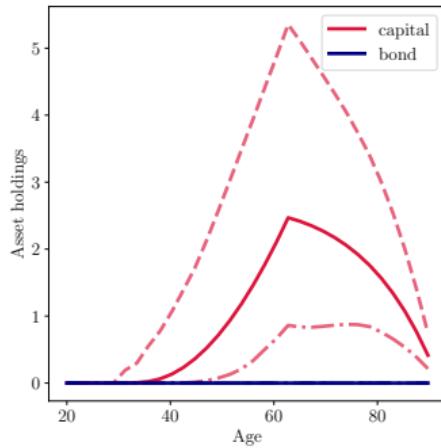

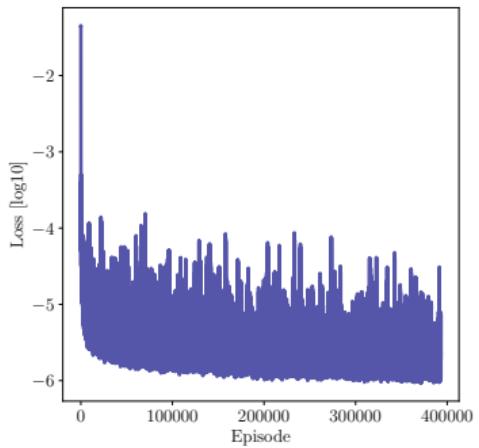

- With **market clearing policies**, we have a **closed form expression for the bond price** and can define pre-train price and error

$$p_t^{b,\text{pretrain}} := \max_{h \in \mathcal{H}} \left\{ \frac{\beta E[u'(c_{t+1}^{h+1})]}{u'(c_t^h)} \right\} \quad (36)$$

$$\epsilon_t^{\text{pretrain}} := p_t^{b,\text{pretrain}} - \hat{p}_t^b \quad (37)$$

- Loss function

$$\ell_\rho(\mathbf{x}_t) := \underbrace{1 \times \left(\sum_{h=1}^{H-1} \left(\epsilon_t^{k,h} \right)^2 \right)}_{\text{opt. cond. cap.}} + \underbrace{0 \times \left(\sum_{h=1}^{H-1} \left(\epsilon_t^{b,h} \right)^2 \right)}_{\text{opt. cond. bond}} + \underbrace{1 \times \left(\epsilon_t^{\text{pretrain}} \right)^2}_{\substack{\text{price pretrain error} \\ \text{train supervised}}} \quad (38)$$

Step 3: slowly increase bond supply

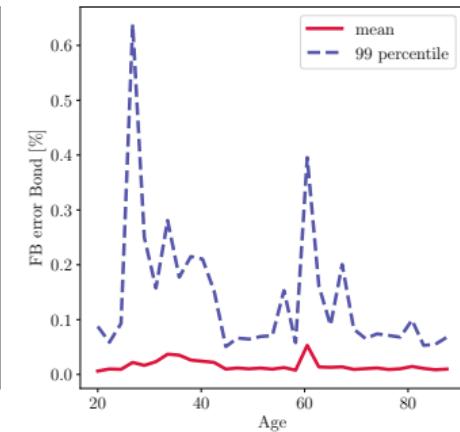

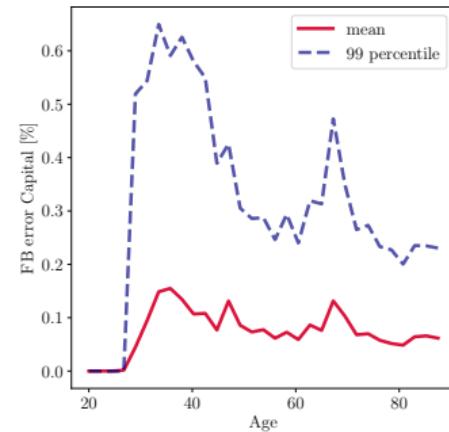

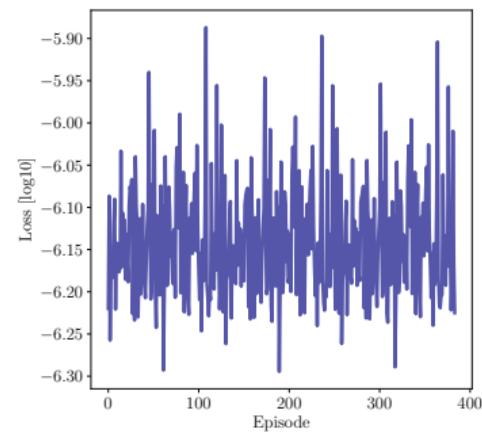

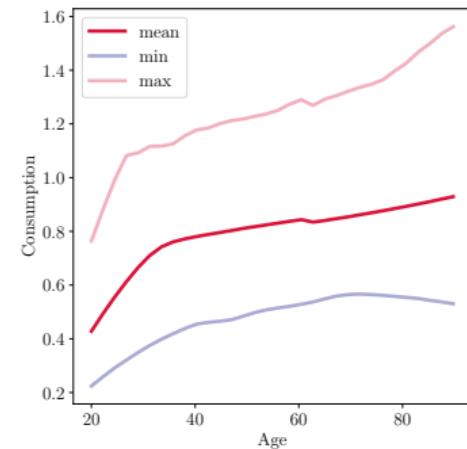

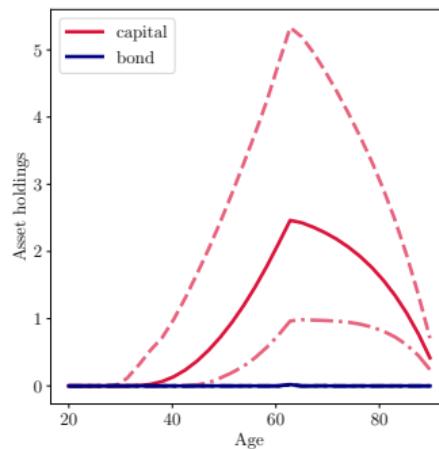

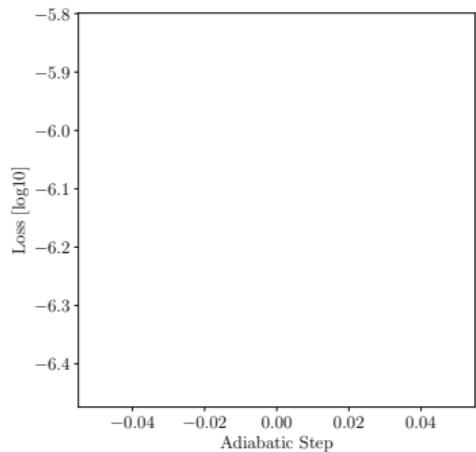

- Borrowing constraint $\underline{b} = 0$, increase net-supply from $B = 0.1$ to $B = 10$
- Neural network predicts

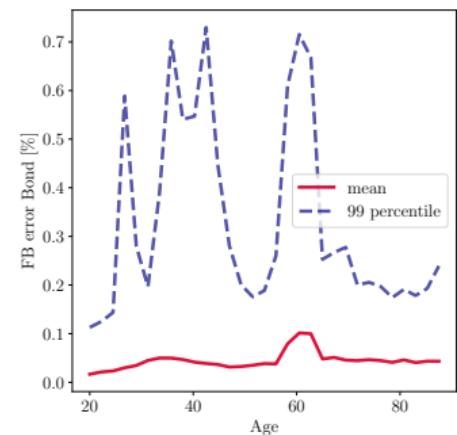

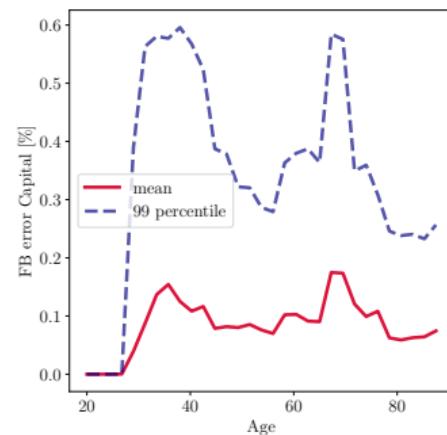

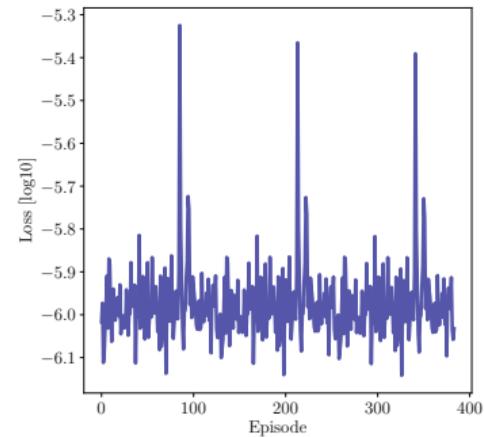

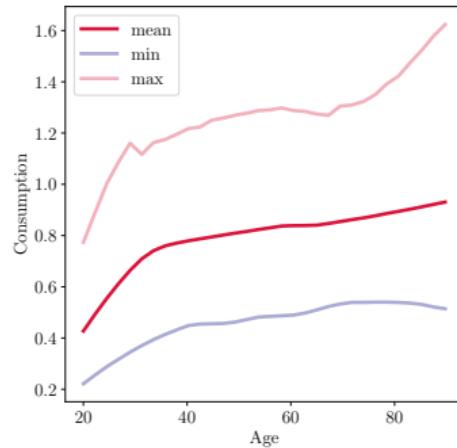

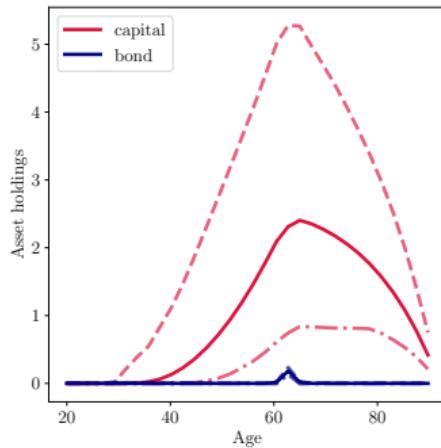

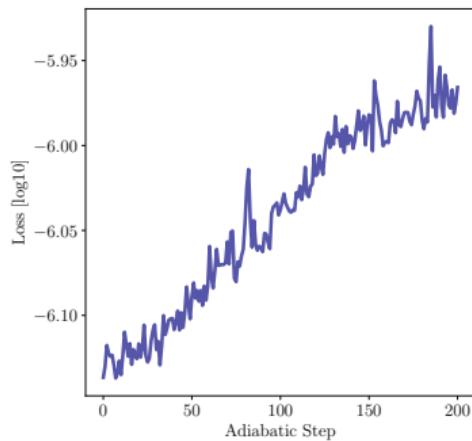

$$\mathcal{N}_\rho^{\text{pre}}(\mathbf{x}_t) = [\hat{k}_{t+1}^1, \dots, \hat{k}_{t+1}^{32}, \underbrace{0.01 \times \tilde{b}_{t+1}^1, \dots, 0.01 \times \tilde{b}_{t+1}^{32}}_{\text{bond policies active}}, \hat{p}_t^b] \quad (39)$$

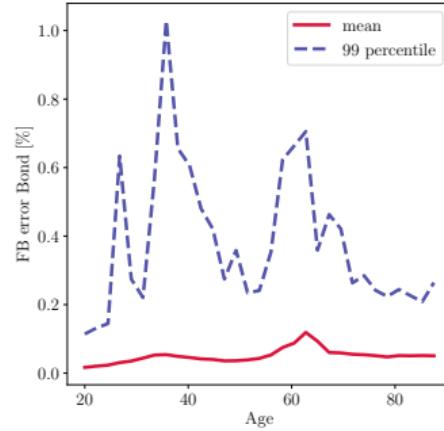

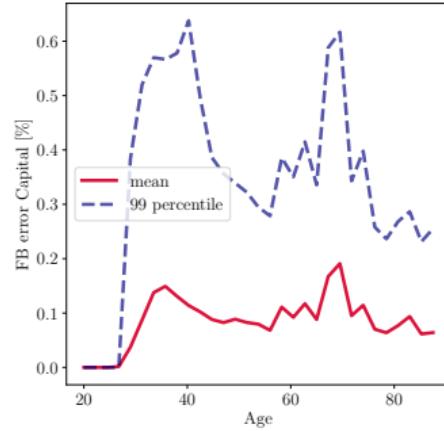

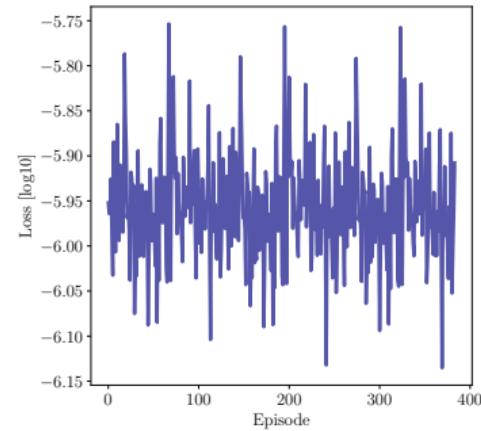

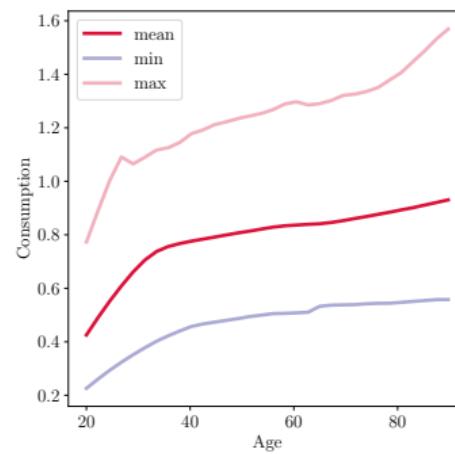

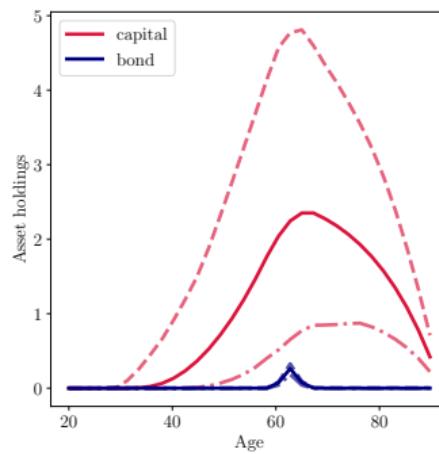

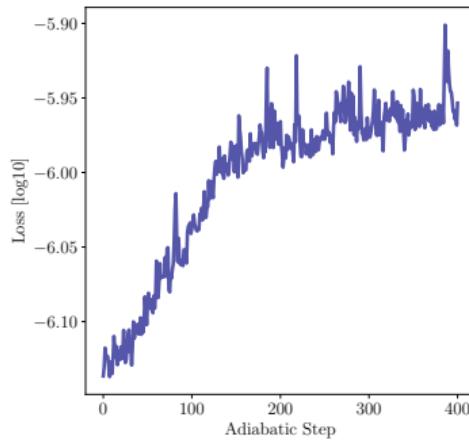

$$\Rightarrow \mathcal{N}_\rho(\mathbf{x}_t) = [\hat{k}_{t+1}^1, \dots, \hat{k}_{t+1}^{32}, \underbrace{\hat{b}_{t+1}^1, \dots, \hat{b}_{t+1}^{32}}_{\text{always add up the B}}, \hat{p}_t^b] \quad (40)$$

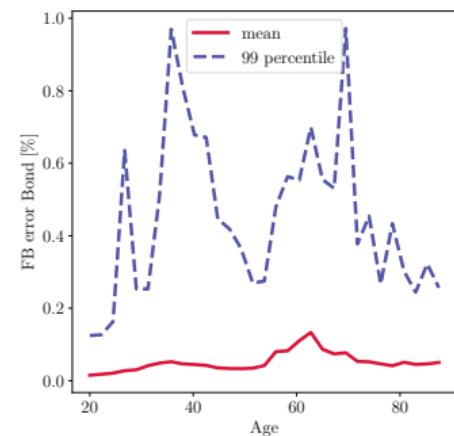

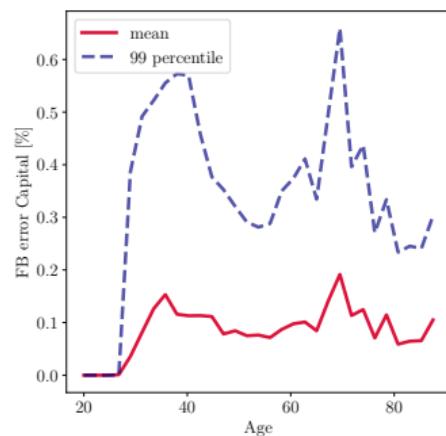

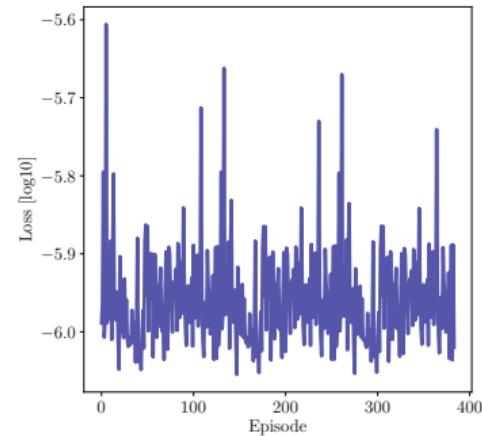

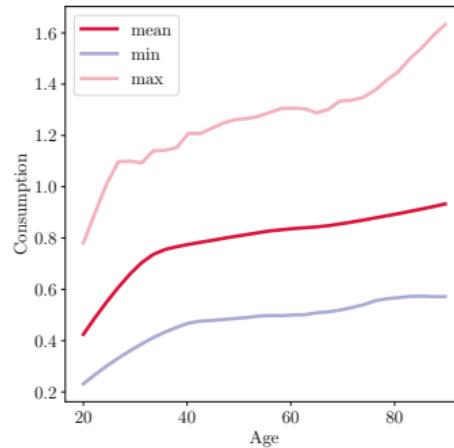

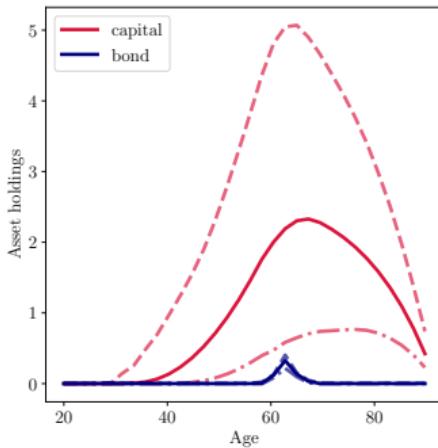

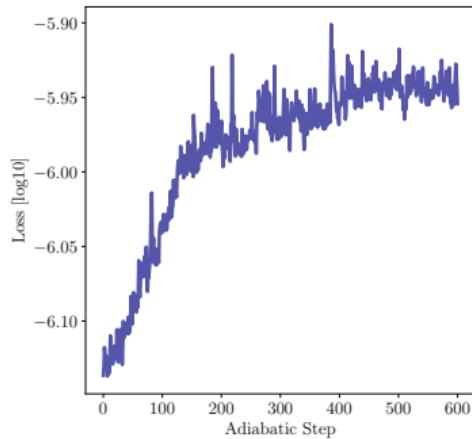

- Loss function

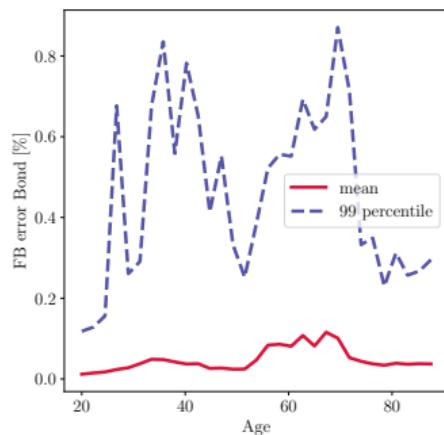

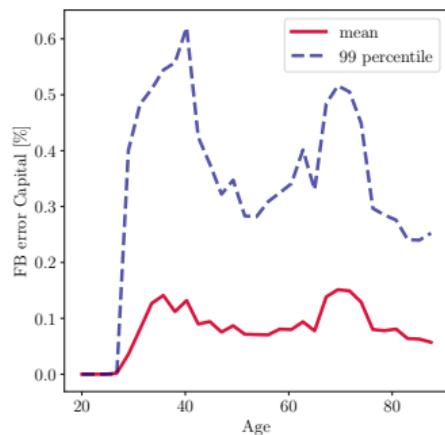

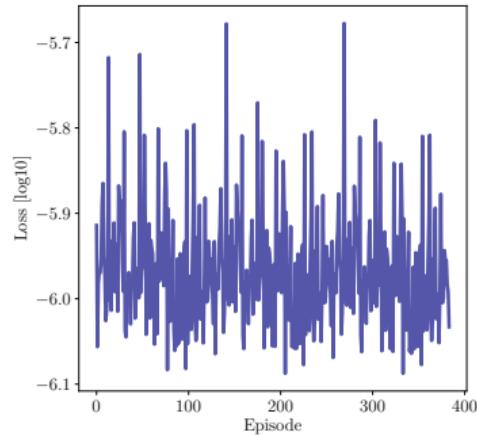

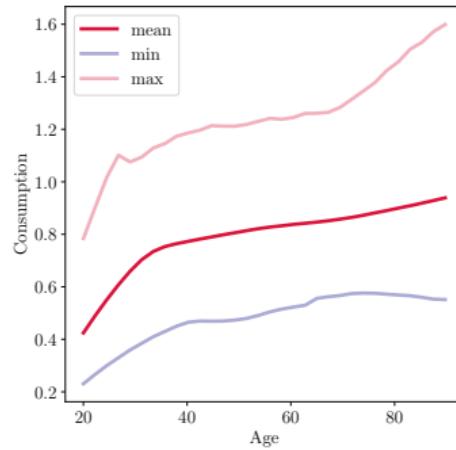

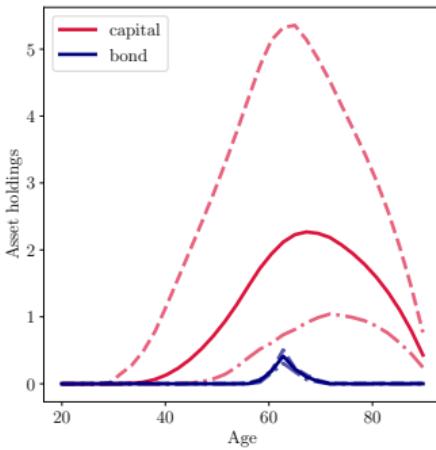

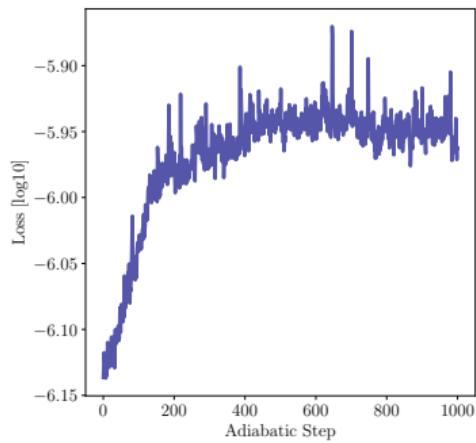

$$\ell_\rho(\mathbf{x}_t) := \underbrace{1 \times \left(\sum_{h=1}^{H-1} (\epsilon_t^{k,h})^2 \right)}_{\text{opt. cond. cap.}} + \underbrace{1 \times \left(\sum_{h=1}^{H-1} (\epsilon_t^{b,h})^2 \right)}_{\text{bond equ. cond. active opt. cond. bond}} \quad (41)$$

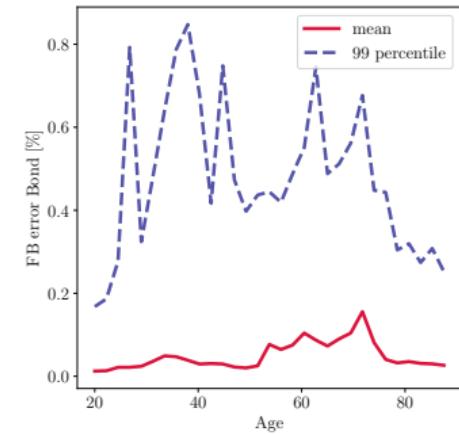

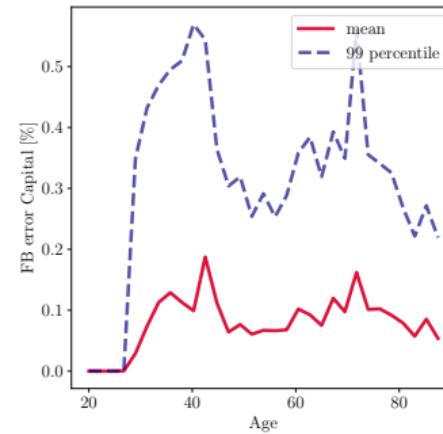

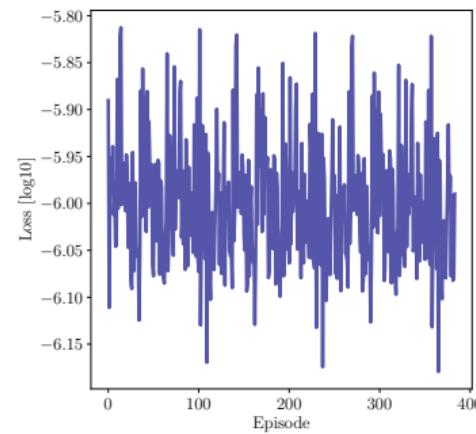

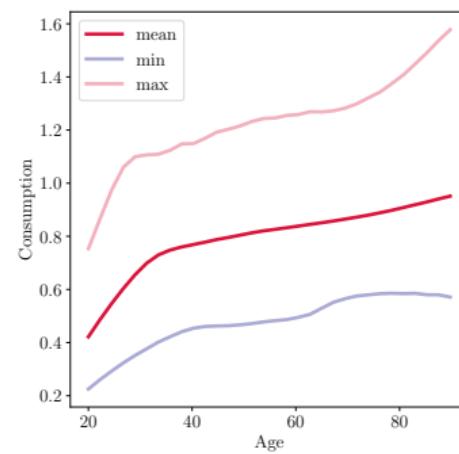

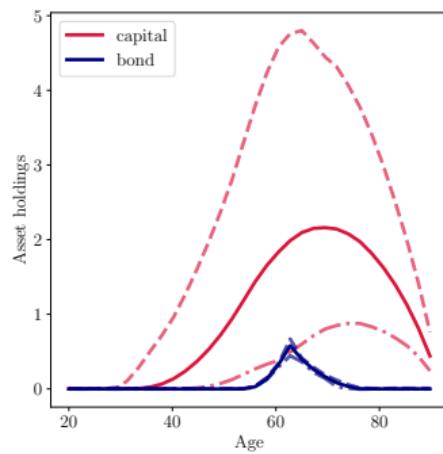

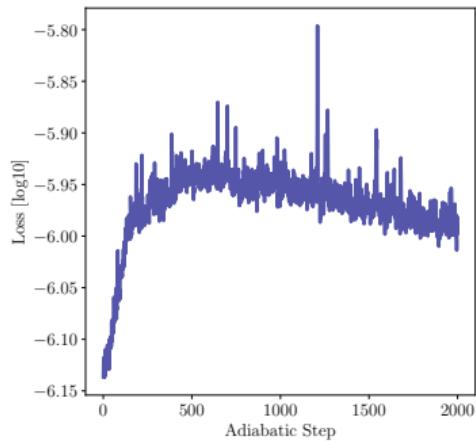

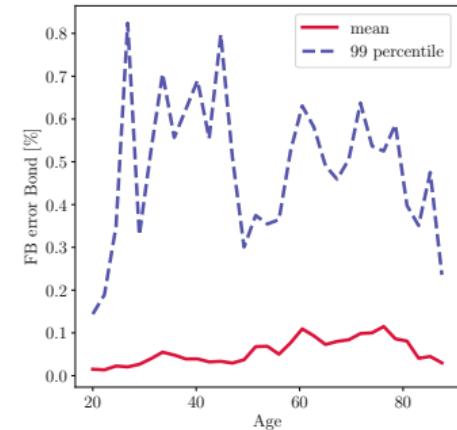

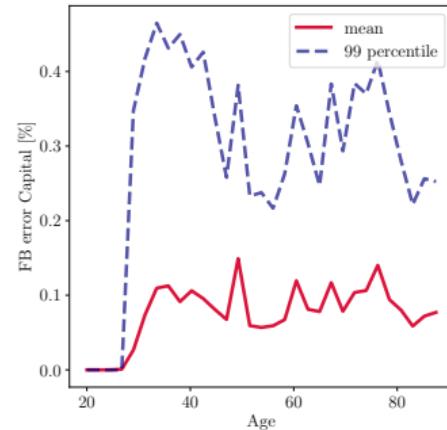

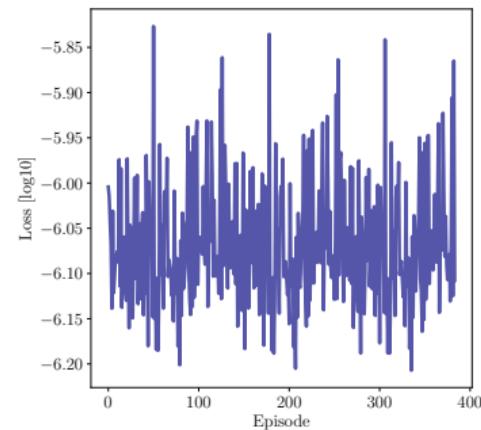

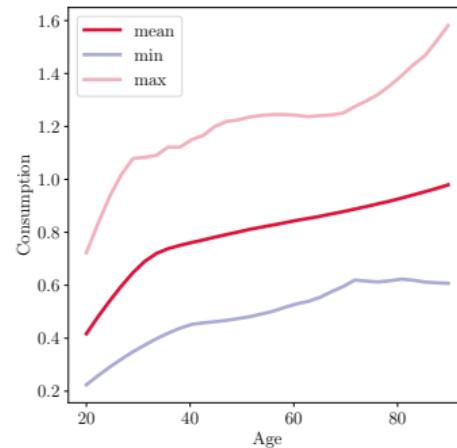

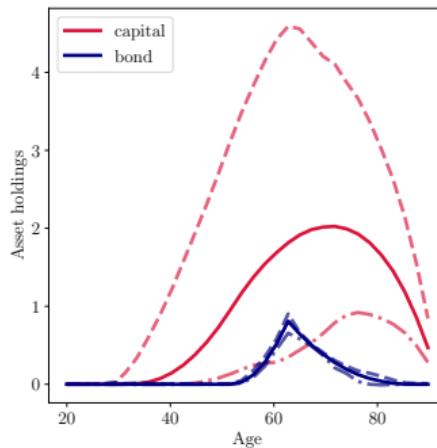

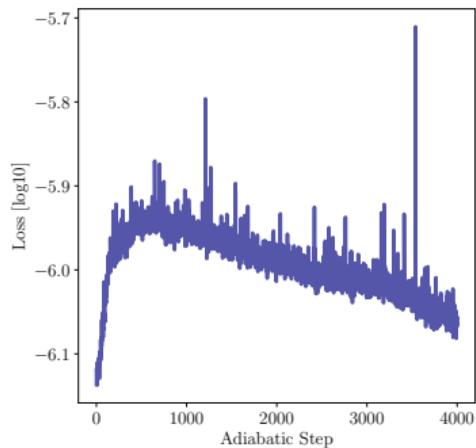

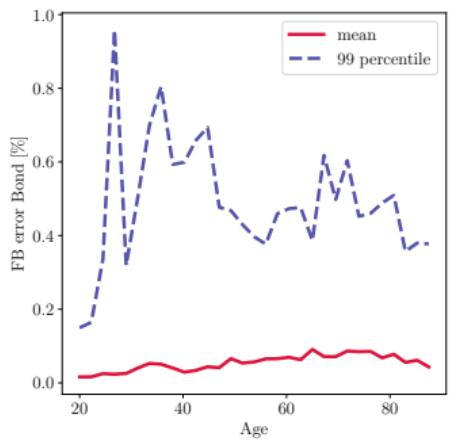

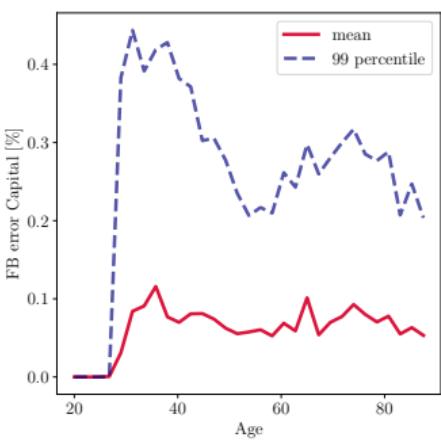

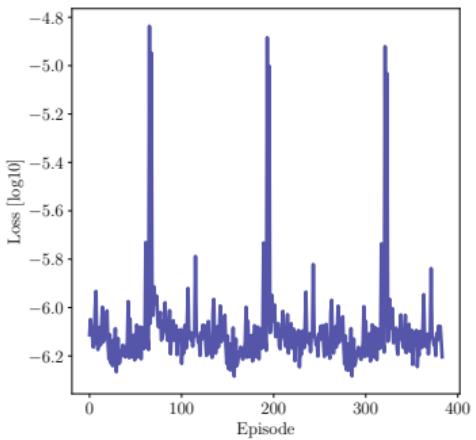

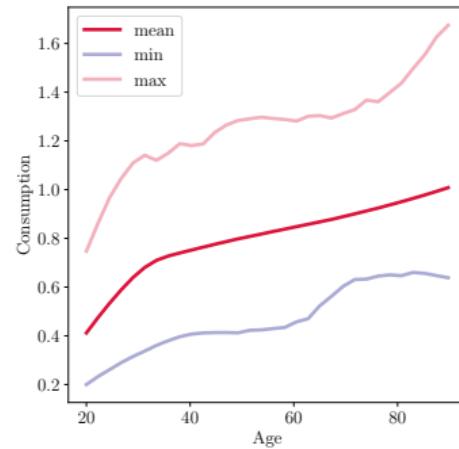

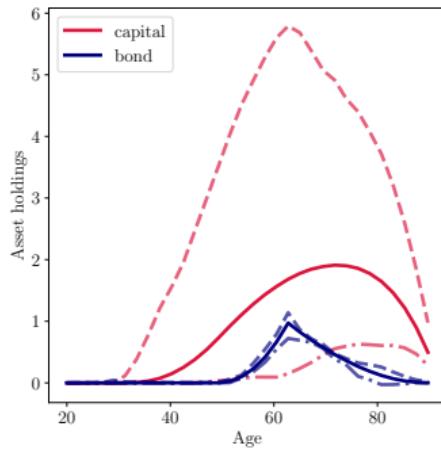

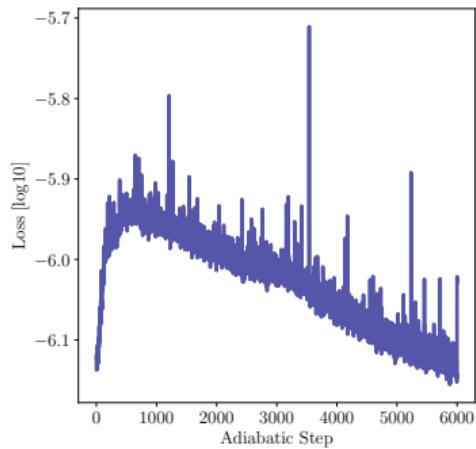

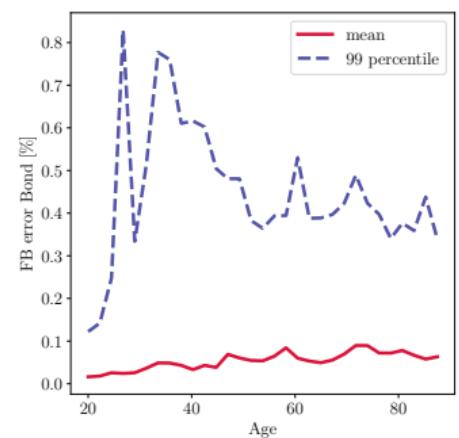

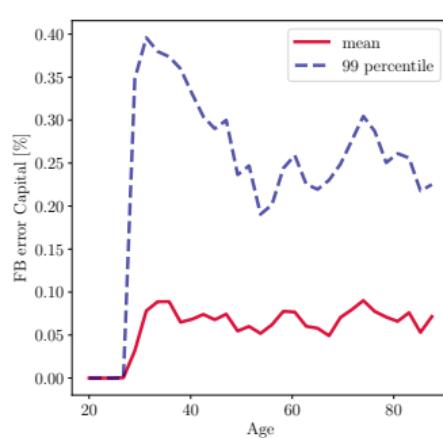

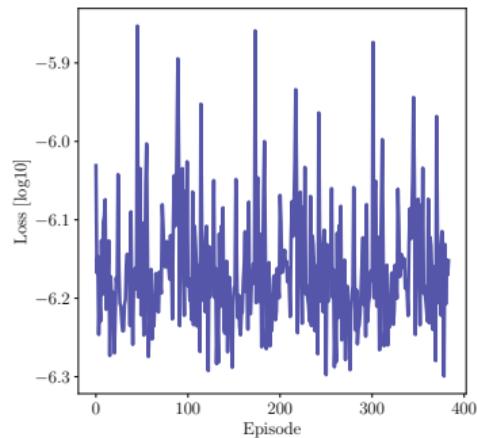

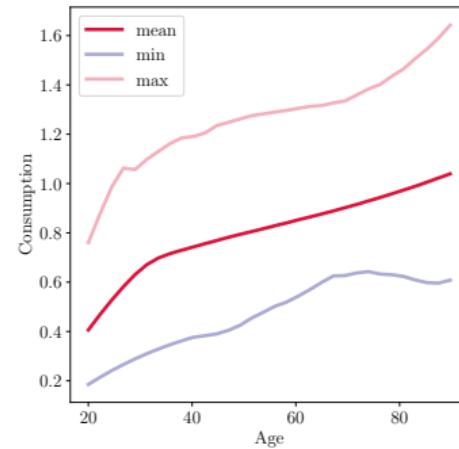

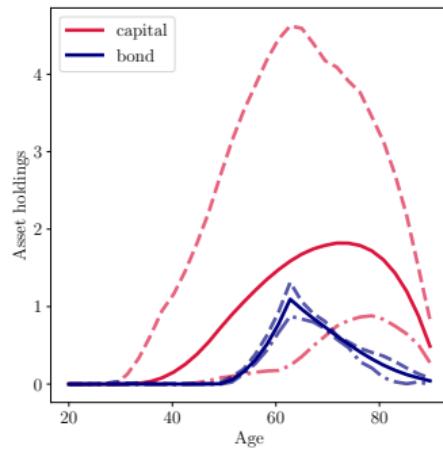

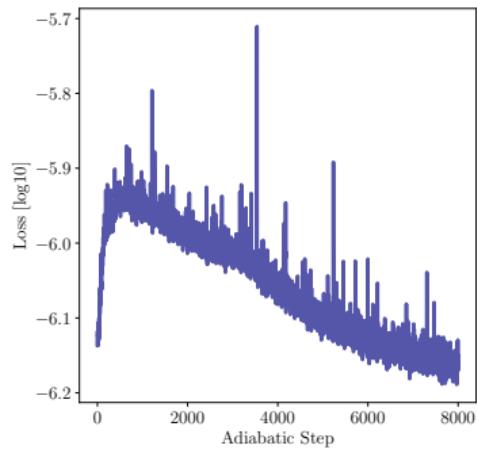

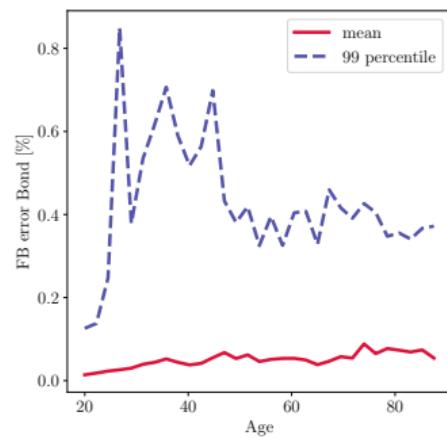

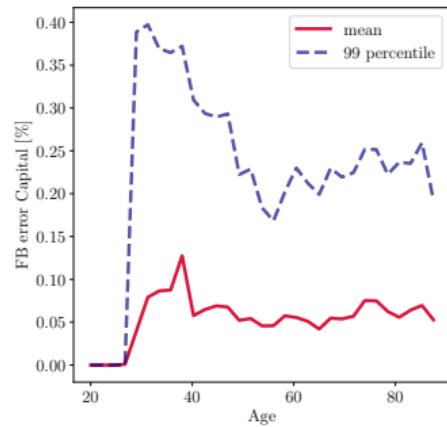

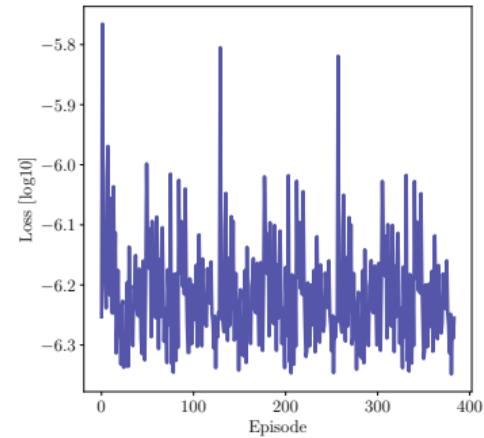

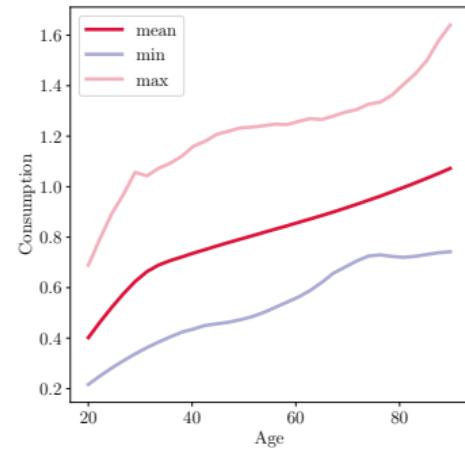

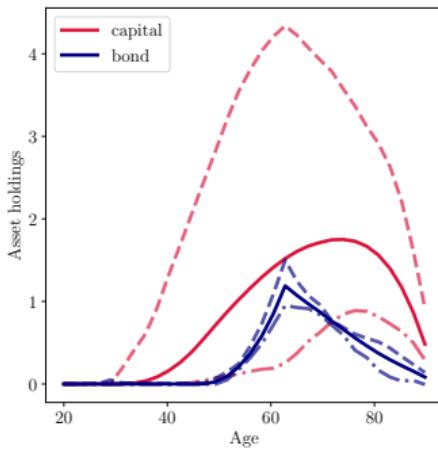

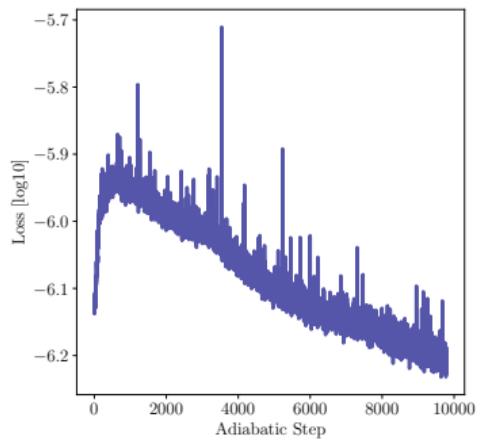

Step 4: some more training with the final supply

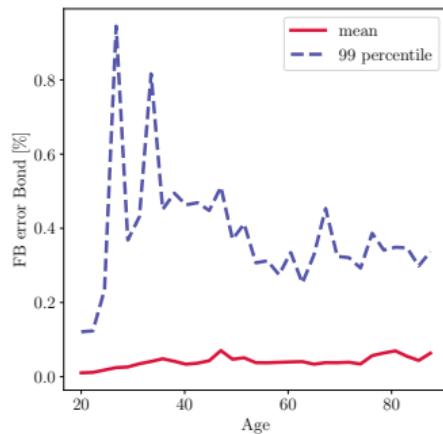

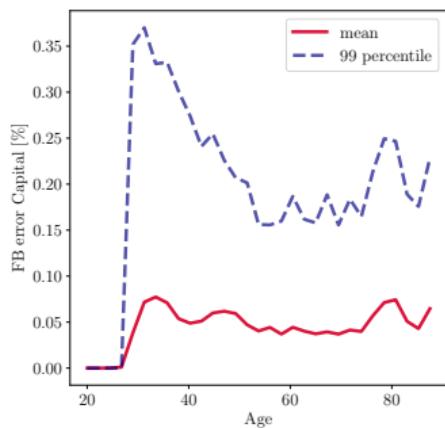

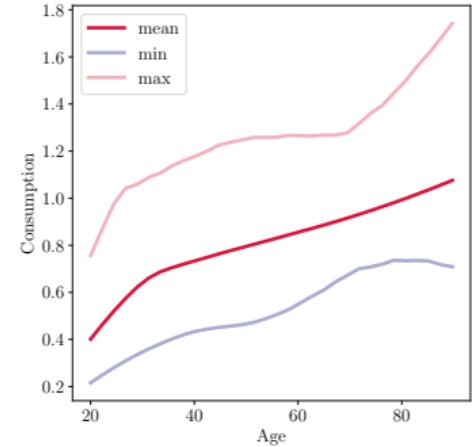

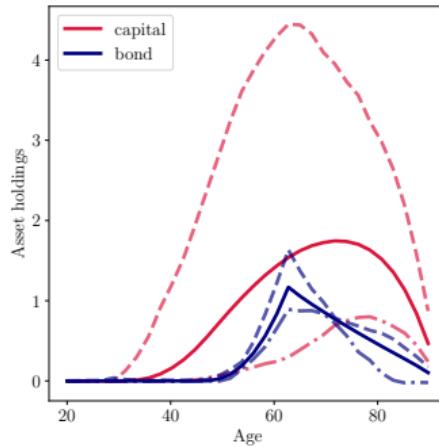

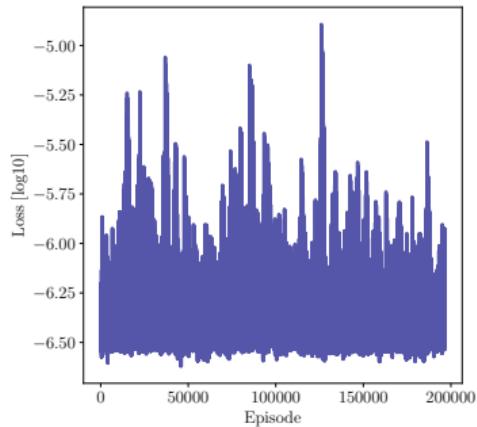

- ▶ Borrowing constraint $\underline{b} = 0$, bond at full net-supply from $B = 10$
- ▶ Neural network predicts

$$\mathcal{N}_\rho^{\text{pre}}(\mathbf{x}_t) = [\hat{k}_{t+1}^1, \dots, \hat{k}_{t+1}^{32}, \underbrace{0.01 \times \tilde{b}_{t+1}^1, \dots, 0.01 \times \tilde{b}_{t+1}^{32}}_{\text{bond policies active}}, \hat{p}_t^b] \quad (42)$$

$$\Rightarrow \mathcal{N}_\rho(\mathbf{x}_t) = [\hat{k}_{t+1}^1, \dots, \hat{k}_{t+1}^{32}, \underbrace{\hat{b}_{t+1}^1, \dots, \hat{b}_{t+1}^{32}}_{\text{always add up the B}}, \hat{p}_t^b] \quad (43)$$

- ▶ Loss function contains all remaining equilibrium conditions

$$\ell_\rho(\mathbf{x}_t) := \underbrace{1 \times \left(\sum_{h=1}^{H-1} (\epsilon_t^{k,h})^2 \right)}_{\text{opt. cond. cap.}} + \underbrace{1 \times \left(\sum_{h=1}^{H-1} (\epsilon_t^{b,h})^2 \right)}_{\text{opt. cond. bond}} \quad (44)$$

More Challenging Application

Model

Additional to capital and bond as in simple model:

- ▶ Include **fluctuations in the size of the incoming cohort**
 - ▶ size of incoming cohort m_t^1 follows an AR(2)
 - ▶ mass-distribution $[m_t^1, \dots, m_t^H]$ becomes start of the state-space
 - ▶ expectation now over ϵ_{t+1}^m and ϵ_{t+1}^Z
- ▶ Add **land** as a third asset
 - ▶ Production function: $Y_t = Z_t K_t^{\alpha_K} L_t^{\alpha_L} N_t^{1-\alpha_K-\alpha_L}$
 - ▶ additional asset price: p_t^L
 - ▶ $H - 1$ new state-variables: I_t^h
 - ▶ $H - 1$ new policies: I_{t+1}^{h+1}
 - ▶ $H - 1$ new optimality conditions: FOC's for land choice
- ▶ Introduce **Epstein Zin utility**
 - ▶ need to approximate $H - 1$ value functions: V_t^h
 - ▶ $H - 1$ new equilibrium conditions: Bellman equations
- ▶ Adjustment costs on aggregate capital (via a financial intermediary)

Model

- State of the economy:

$$\mathbf{x}_t = [\underbrace{Z_t}_{\text{TFP}}, \underbrace{m_t^1, \dots, m_t^H}_{\text{mass distribution}}, \underbrace{k_t^1, \dots, k_t^H}_{\text{capital distribution}}, \underbrace{b_t^1, \dots, b_t^H}_{\text{bond distribution}}, \underbrace{l_t^1, \dots, l_t^H}_{\text{land distribution}}]$$

- Equilibrium functions to approximate

$$\mathcal{N}_\rho(\mathbf{x}_t) \approx \mathbf{f}(\mathbf{x}_t) = [\underbrace{p_t^b, p_t^L}_{\text{prices}}, \underbrace{V_t^1, \dots, V_t^{H-1}}_{\text{value functions}}, \underbrace{k_{t+1}^2, \dots, k_{t+1}^H}_{\text{capital savings}}, \underbrace{b_{t+1}^2, \dots, b_{t+1}^H}_{\text{bond savings}}, \underbrace{l_{t+1}^2, \dots, l_{t+1}^H}_{\text{land savings}}]$$

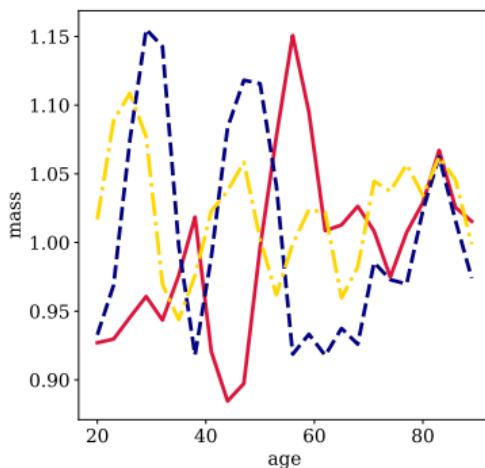

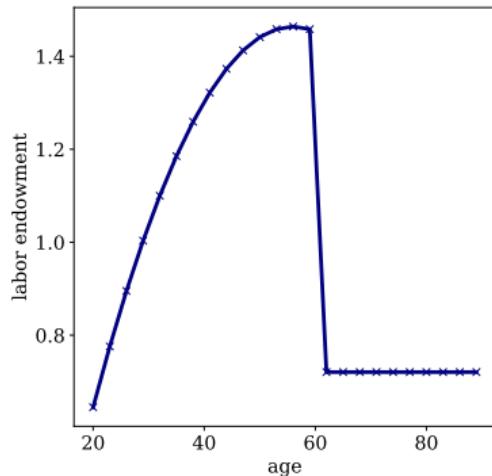

- Loss function

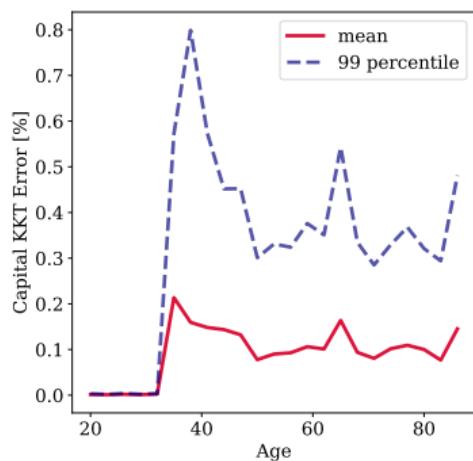

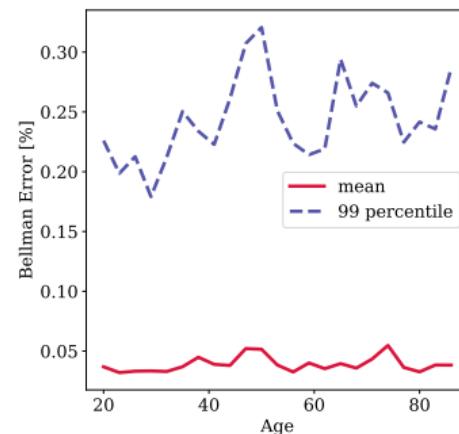

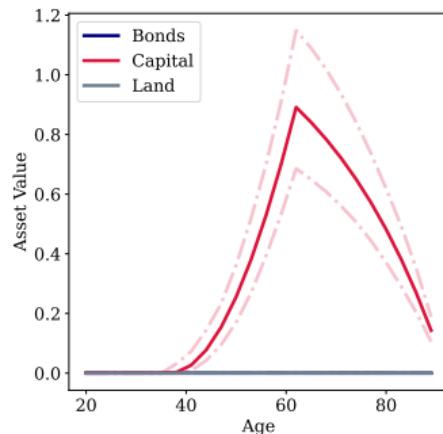

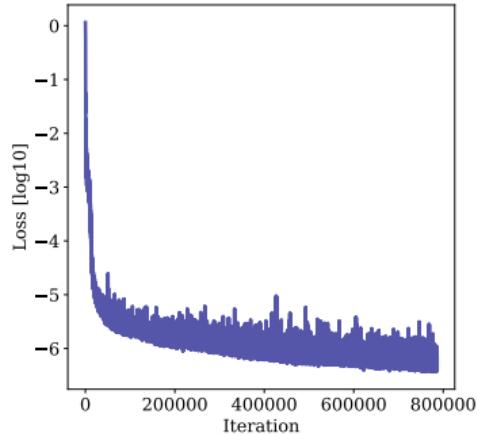

$$\ell_\rho(\mathbf{x}_t) := \underbrace{\left(\sum_{h=1}^{H-1} (\epsilon_t^{k,h})^2 \right)}_{\text{opt. cond. cap.}} + \underbrace{\left(\sum_{h=1}^{H-1} (\epsilon_t^{b,h})^2 \right)}_{\text{opt. cond. bond}} + \underbrace{\left(\sum_{h=1}^{H-1} (\epsilon_t^{l,h})^2 \right)}_{\text{opt. cond. land}} + \underbrace{\left(\sum_{h=1}^{H-1} (\epsilon_t^{\text{Bellman},h})^2 \right)}_{\text{rel. Bellman error}}$$

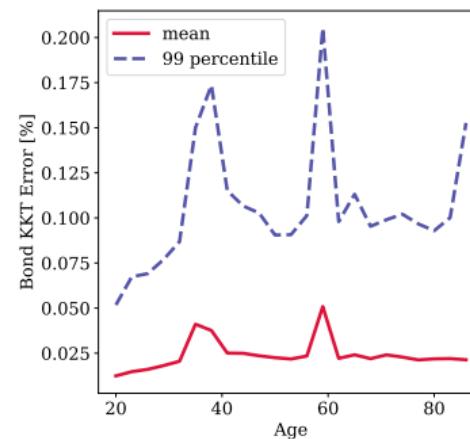

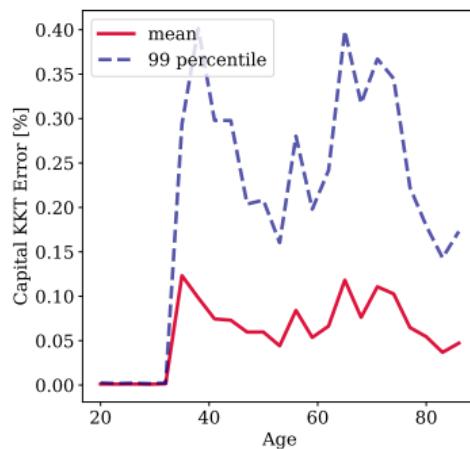

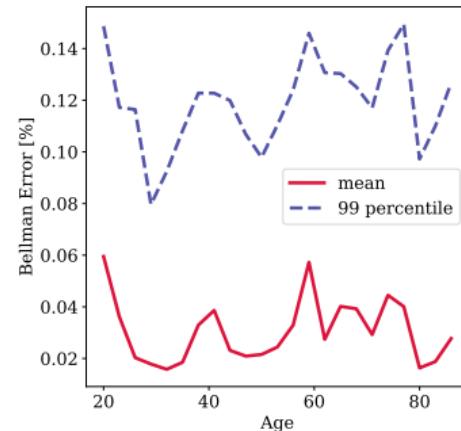

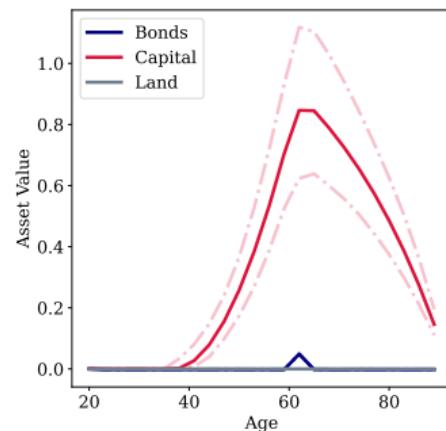

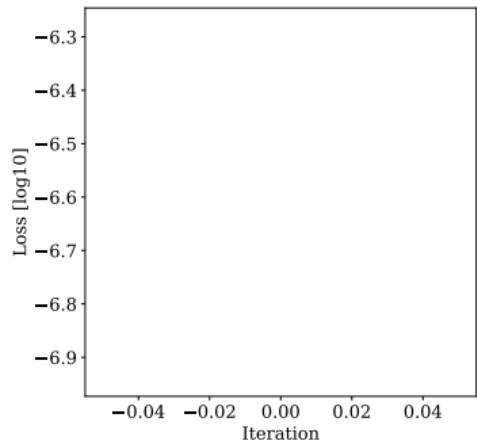

$$+ \underbrace{(\epsilon_t^{MCB})^2}_{\text{market clearing bond}} = 0 \quad + \underbrace{(\epsilon_t^{MCL})^2}_{\text{market clearing land}} = 0$$

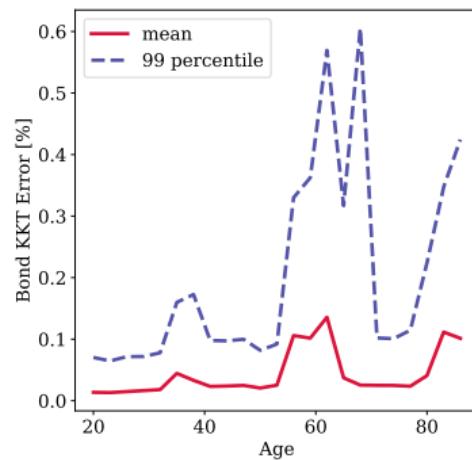

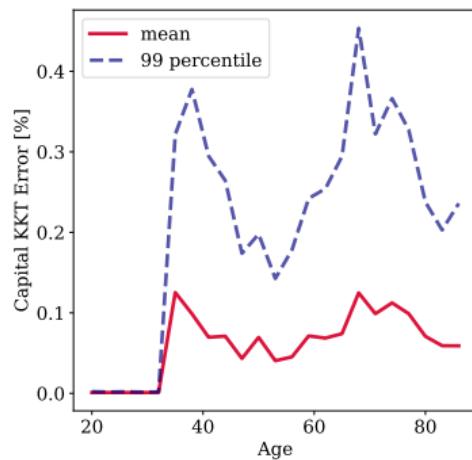

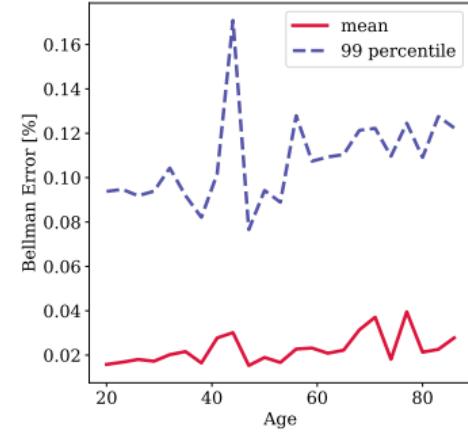

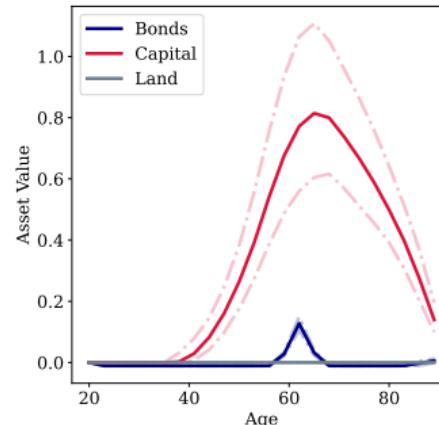

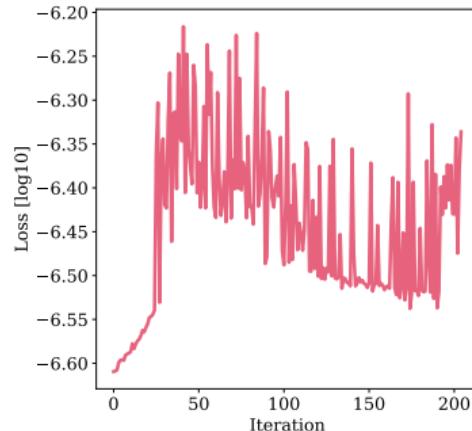

Parameters

Conclusion

- ▶ We develop a deep learning solution method for solving large stochastic models with portfolio choice
- ▶ Two key innovations
 - ▶ **Market Clearing Layers**, an economics-inspired neural network architecture
 - ▶ **Adiabatic model transformation** procedure to guide network training with many assets

Thank you!

Deep Neural Networks

What is a deep neural net?

► DEQN

A neural net is a sequence of affine models interleaved by element-wise nonlinear transformations

$$\begin{aligned}\text{input} &:= \mathbf{x} \rightarrow \phi^1(W_\rho^1 \mathbf{x} + \mathbf{b}_\rho^1) =: \text{hidden 1} \\ &\rightarrow \text{hidden 1} \rightarrow \phi^2(W_\rho^2(\text{hidden 1}) + \mathbf{b}_\rho^2) =: \text{hidden 2} \\ &\rightarrow \text{hidden 2} \rightarrow \phi^3(W_\rho^3(\text{hidden 2}) + \mathbf{b}_\rho^3) =: \text{output}\end{aligned}$$

The neural net is given by the choice of activation functions $\{\phi^i\}$ and the parameters ρ .
