

An aerial photograph of Tokyo, Japan, taken at dusk. The Tokyo Tower is the central focus, illuminated with warm orange lights. The city's dense urban landscape is visible, with numerous skyscrapers and buildings. The sky is a deep blue with some light clouds. A thin orange horizontal line is drawn across the middle of the image, passing behind the text.

From Samurai to Skyscrapers: How Transaction Costs Shape Tokyo

Junichi Yamasaki (Kobe, Hitotsubashi TDB-CAREE)

Kentaro Nakajima (Hitotsubashi)

Kensuke Teshima (Hitotsubashi)

2023/Aug EEA-ESEM

Motivation

- City is the center of economic activities.
- Efficient use of the scarce land in the CBD can have a sizable impact on the functioning of the economy.
- Land ownership should be continuously allocated to the best usage at that time.
- One key type of land transaction is to change lot size by split or assembly. But, transaction costs might exist:
 - Land assembly will also be costly because negotiation with multiple landowners is needed.
 - Land split will also be costly because demolishing the buildings and finding multiple buyers to sell split land are necessary.

Motivation

- City is the center of economic activities.
- Efficient use of the scarce land in the CBD can have a sizable impact on the functioning of the economy.
- Land ownership should be continuously allocated to the best usage at that time.
- One key type of land transaction is to change lot size by split or assembly. But, transaction costs might exist:
 - Land assembly will also be costly because negotiation with multiple landowners is needed.
 - Land split will also be costly because demolishing the buildings and finding multiple buyers to sell split land are necessary.

Motivation

- If transaction costs $>$ benefit of optimal land use
→ lot size can persist and affect urban development in the long run (Coase, 1960)
- Lot size persistence
 - Rural/agricultural settings: lot size persistence disappears in 150 years (Bleakley and Ferrie, 2014; Smith, 2020; Finley et al., 2021)
 - Can we expect the same pattern in cities?
 - Benefit of optimal land use \uparrow → Weaker persistence?
 - Transaction costs \uparrow → Stronger persistence?
- Urban development
 - Consequence of lot size persistence for urban development is understudied and can be different in space and time
 - Once tall buildings become available: tall buildings require large footprints and generate agglomeration benefits → premia

Motivation

Our study: History of Tokyo as a laboratory

- This study examines how the initial lot size affects urban development in the long run, in the context of central Tokyo.
- Natural experiment: **release of local lords' estates** (*daimyo yashiki*) to the private market after 1868
 - Local lords (*daimyo*) are the chiefs of about 300 regional domains in Japan. They owned estates in Tokyo.
 - Local lords' estates are much larger than other lots.
 - → They lost their estates and the private sector took over them after 1868
 - → Supply shock of larger lots to Tokyo.
 - Spread across Tokyo + a zoning episode for RD

 - Spread across Tokyo + a zoning episode for RD

One example from a map in 1850s: Tamachi Station

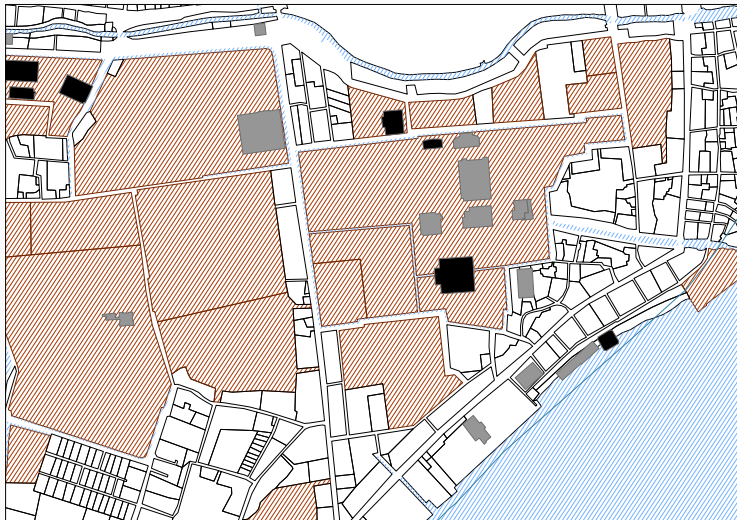

Local lords' estates are less-fragmented (1850s)

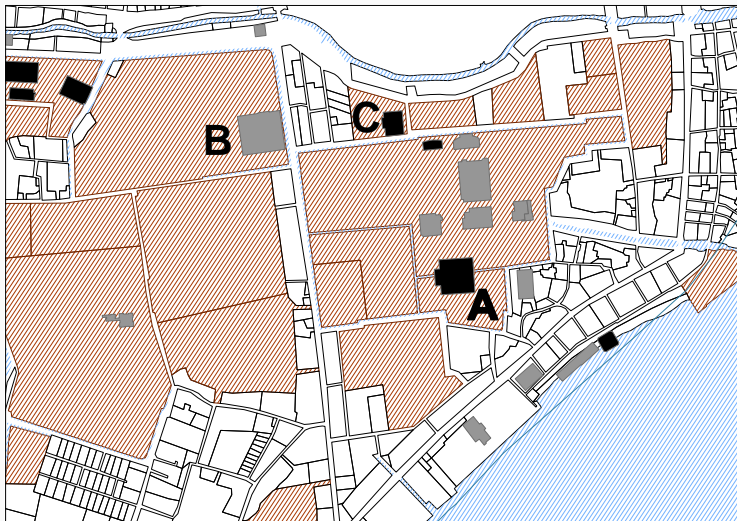

Those lots are less fragmented even today (2010)

And tall buildings (> 15 or > 30 stories) are there (2011)

And tall buildings (> 15 or > 30 stories) are there (2011)

Large variation of building heights in a small area suggesting high land assembly costs

Very brief summary of history

- 1600: *Shogun* started to construct a city in a marsh.
- During the pre-modern era (1600–1868): 250-300 local feudal lords
- Local lords typically had three estates (Larger lots)
 - Wives and kids stayed in Tokyo as hostages
 - "Alternate Attendance System": Lords had to come to Tokyo once a two years and stay for a year
 - Vassals stayed in Tokyo as well
- 1868: Two estates were expropriated → mostly released to the private market
- After WWII: heavy asset tax rate so that they had to sell the remaining one

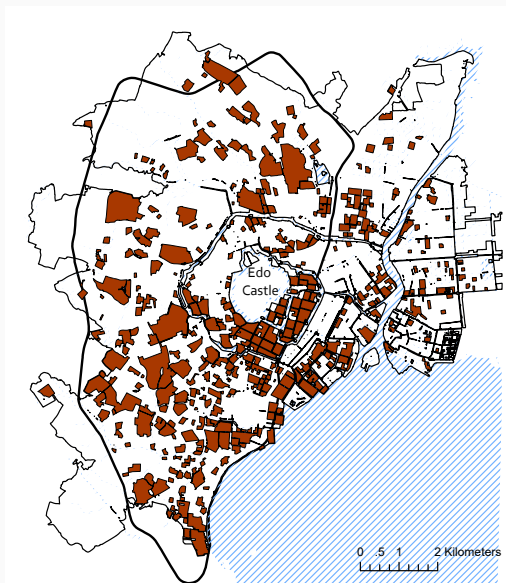

Local lords as chiefs of local domains

Very brief summary of history

Urbanization of old Tokyo

- Business activities increased in old Tokyo after WWII.
- After WWII, daytime population increased from 3M to 4.7M.
 - Residential population did not increase so much.
- Tall buildings increased.
 - No skyscrapers before 1965
 - Kasumigaseki building in 1965 = 36 stories, 147 m
 - Over-30-stories buildings: 32 in 1990, 86 in 2000, 260 in 2010, and 357 in 2020

Data spanning 150 years

- Various data sources including digitizing new data
 - Local lords' estates in the 1850s
 - Lot fragmentation in 1873, 1912, 1931–35, and 2008–2011.
 - Land price in 1876, 1912, 1931-1935, 1972, 1983, 2010s.
 - Buildings of today (shape, height, sector, ..)
- We aggregate all of these information at the 100 m*100 m cell level.

5 Conclusion & Related Literature

Various Identification Strategies

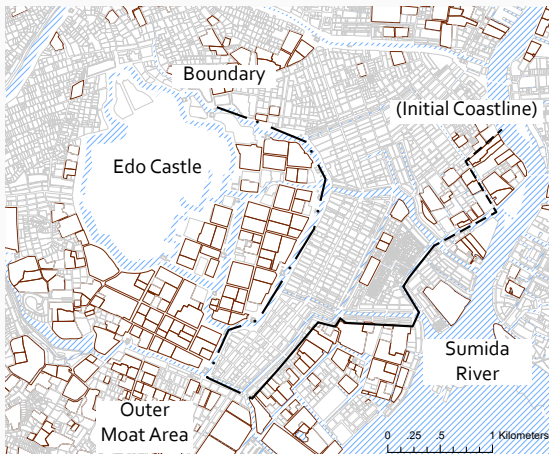

- OLS conditional on geographical controls
- Higher local lords' estates share → In 2011, less lot fragmentation, more tall buildings, and higher land prices.
 - When local lords' estates share increases from zero to one, land price increases by 17–30 %.
- RD using zoning policy

Core vs Non-core

- Persistence in spite of high economic potential in the core area: high transaction costs
 - higher potential gain may endogenously intensify landowner's strategic behavior in their negotiation (the hold-out problem, (Miceli and Sirmans, 2007; Brooks and Lutz, 2016; Grossman et al., 2019)
 - Heterogeneous land use and land owners → collective action is hard (Olson, 2003)
- City planners should care transaction costs seriously because it can hinder the development of the CBD.

Firm-level micro data to investigate agglomeration benefits

- Local lords' estates → skyscrapers (→ agglomeration benefits for firms) → higher land price
- Firm-level data collected by a major Japanese credit research company (Teikoku Databank).
 - Cover most of the Japanese firms
 - Revenue per worker (proxy of TFP)
 - Location of HQ
- Selection vs Agglomeration
 - Selection will affect the lower tail of productivity, while agglomeration will shift the distribution or make the upper tail ticker (Combes et al., 2012).

 - Revenue per worker (proxy of TFP)
 - Location of HQ
- Selection vs Agglomeration
 - Selection will affect the lower tail of productivity, while agglomeration will shift the distribution or make the upper tail ticker (Combes et al., 2012).

The upper tail is thicker and the lower tail does not show clear cutoff

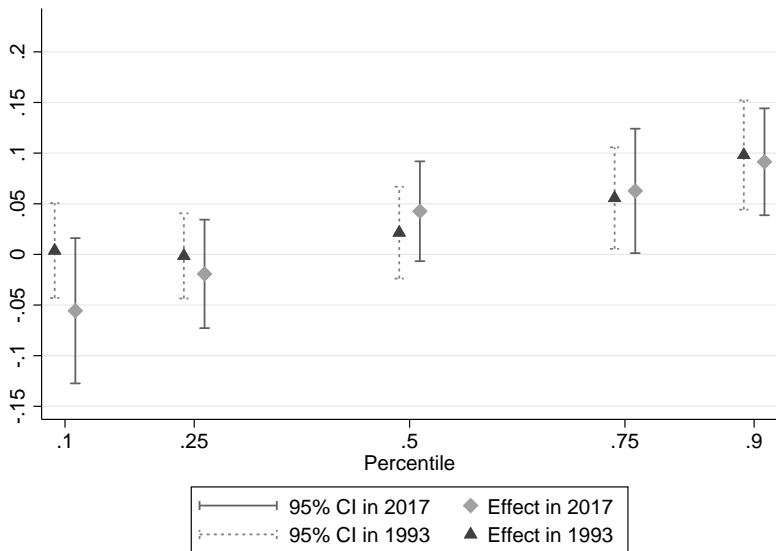

Larger impacts in the upper tail using 2017

Impacts are smaller in 1993 when buildings were shorter

Impacts become similar when controlling for stories

Robustness Checks

- Main results: Local loads estates → Larger lot size → Skyscrapers → Higher land price
 - Public infrastructure, not skyscrapers? → Table A.14 and A.15 in the paper
 - Block size, not lot size? → Table A.16 and A.17
 - Remaining estate? → Table A.18
 - Initial land price, not lot size? → Table A.19 and A.20
 - Coefficient stability analysis → Table A.5 and A.8
- Construction technology and office economy after WWII → Larger lots are more valued
 - Destruction by bombing in WWII? (This might affect results about inside vs outside the core area as well) → Table A.21–A.24.
 - Transform of military land use to non-military land use? → Table A.25 and A.26
 - Loss of their political privilege & tax base increase? → Table A.27 and A.28

Summary

- Local lords' estates at the end of the 1850s → larger lots in 1917, 1931, and even 2011 (OLS and Local randomization) .
 - Lot size persistence only in the core area, suggesting high transaction costs in the core area.
- Local lords' estates at the end of the 1850s → taller buildings, and higher land prices today.
 - Negative effect on land price (split cost) before WWII
 - It turned to positive around the 1970s
 - Positive effect on firm productivity by tall buildings.
 - → The benefits of large lots depends on the available construction technology.
- Land ownership at the initial stage of modern economic development affects the shape of a city today by high transaction costs.
