Contributed Session: Income Inequality
August 27, 2024

What we do not know about spatial inequality

- How much does spatial wage inequality contribute to **national wage inequality**?
- How does spatial wage inequality **compare across countries**?
- How has spatial wage inequality **evolved through time**?
- What are possible **drivers** of spatial wage inequality?
- Inequality in **wages vs. other sources of income**?

*And of course a lot more but this is what our project is aiming to answer in the first stage.

◀ Some literature

This paper in a nutshell

- Contribution of places in explaining **national inequality** is low and mostly consistent over time
- **Spatial inequality** roughly doubled since the 1980s
 - The US is the most unequal country; and experienced the largest increase
 - Divergence of high wages and convergence of the lowest wages between areas
- **Drivers:** Large places are key in understanding some of the trends

* Results are preliminary and work in progress.

◀ Current stage and project goals

Data

- **Countries:** Canada, US, France, (West) Germany, and the UK from around 1975 to 2019
- **Data:** Social security records and censuses [◀ Details](#)
 - 1-20% sample of the working population
- **Population:** Adult (age 20+) full-time workers
- **Wages:** Pre-tax weekly/daily earnings

*Every mention of Germany from here on refers to West Germany unless stated otherwise.

Definition of economic regions

Local labour market areas (LLMAs):

- Focus: Self-containment of commuting flows (minimize the commuting flows across area boundaries)
- Includes: Urban and rural areas (i.e., the whole spatial extent of a country)

◀ Details

National wage inequality

Importance of places for national inequality

Raw Variance Share (RVS): For each year, we calculate R^2 from:

$$\ln(\text{wage}_{irt}) = \alpha_t + \mu_{rt} + \varepsilon_{irt}$$

where i denotes the individual, r the LLMA, t is time and μ_{rt} LLMA fixed effects.

RVS is the percentage of variance in wages **accounted for by the variance of mean wages between areas.**

◀ Trends in national inequality

Between-inequality contributes a rather low share

Full-time workers, 20+ years old, weekly earnings. Source: UK: ASHE/NESPD; DE: SIAB; FR: DADS; CA: CCP; US: Census/ACS

- Place relatively more important in UK/US/FR; stronger rise in UK
- Reunified Germany in 1992: 14%

Spatial wage inequality

Spatial wage inequality

Convergence/divergence across LLMAs:

- Variance of log (i) mean (ii) p90, and (iii) p10 wages
- Drivers: The role of LLMA size
- Drivers: Worker's spatial distribution and the largest LLMAs

* All statistics are weighted by the LLMA population to reduce the effect of small LLMAs.

Convergence/divergence: Mean wages

Full-time workers, 20+ years old, weekly earnings. Source: UK: ASHE/NESPD; DE: SIAB; FR: DADS; CA: CCP; US: Census/ACS.

- Spatial inequality **roughly doubled** in all countries (except France)
- Divergence in 2010s; highest level and increase in the US ◀ What is high?

Convergence/divergence: High wages (P90) vs. low wages (P10)

- p90: increasingly dissimilar in CA/DE/UK/US
- p10: dispersion is low and rather flat over time ◀ Median (p50)
- **Growing spatial inequality is a story of high-wage dispersion (p90)**

The role of LLMA size

- **Growing spatial inequality seems to be a story of high wages... in the largest cities:**
 - Growth in p90 positively correlated with initial city size but not p10 [◀ Details](#)
 - Variance of p90 largely flat once excluding largest LLMA

The role of the largest LLMA: Germany

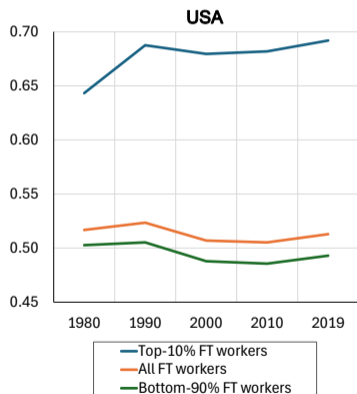

- Dropping the largest LLMA significantly lowers the rise of spatial dispersion of high wages (p90) but not of low wages (p10) ◀ US

Workers' spatial distribution and the largest LLMAs

- **Are workers becoming more spatially concentrated in the big cities?**
- Look at:
 - All workers
 - Top-10% workers
 - Bottom-90% workers

Concentration: Share of full-time (FT) workers in largest 5% LLMA

- Big cities are not growing in workers, **but more high-wage earners live there**

◀ Concentration changes

Conclusion

- Low contribution of places in explaining national inequality, BUT:
- Strong increase in spatial wage inequality
- Divergence for the “rich” and convergence for the “poor”
- Big cities are not growing in workers, but more high-wage earners live there

Future of the project:

- **Conference on spatial inequality in Berlin on December 5 & 6, 2024**
(preliminary) hosted by the Kiel Institute
- 2025: Publicly available database and more papers

Appendix

What we already know about spatial inequalities

Place matters...

- ...for economic outcomes: Moretti (2012)
- ...for political outcomes: Becker et al. (2017)
- ...for happiness and health: De Neve and Krekel (2020); Deryugina and Molitor (2021)

* Just a few examples representing a vast literature each.

Current stage and project goals

Geographic units

- Use similarly defined local labour market areas (LLMAs)

Income

- Wages: social security records + census data (since mid-1970s)
- Total income: income tax returns + census data (since mid-1990s)
- Local costs of living: Build LLMA-level price indices

Sample

- More countries: Full coverage of Western Europe

◀ Go back

Data

Data: matched employee-employer registries + census data

- DE – SIAB – 2% sample of workers (1975-2019) – (West Germany)
- FR – DADS – 4/8% sample of workers (1976-2018)
- UK – NESPD/ASHE – 1% sample of workers (1975-2019)
- CA – CCP – 20% sample of population (1986 – 2016)
- US – Census/ACS – 1% or 5% sample of population (1979 – 2019)

◀ Go back

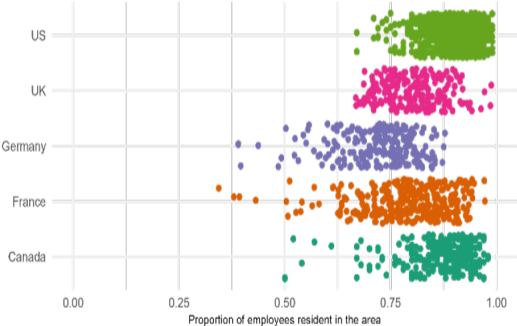

Geographical units: Local Labour Market Areas (LLMAs)

- Canada: 266 self-contained labour market areas
- France: 306 zones d'emploi (employment zones)
- Germany: 223 Arbeitsmarktregionen (labour market regions)
- UK: 228 travel to work areas (imputed using the 'Dorn method' for pre-1997)
- US: 741 commuting zones (imputed using the 'Dorn method')

◀ Go back

Geographical units: Self-contained LLMAs

Demand self-containment

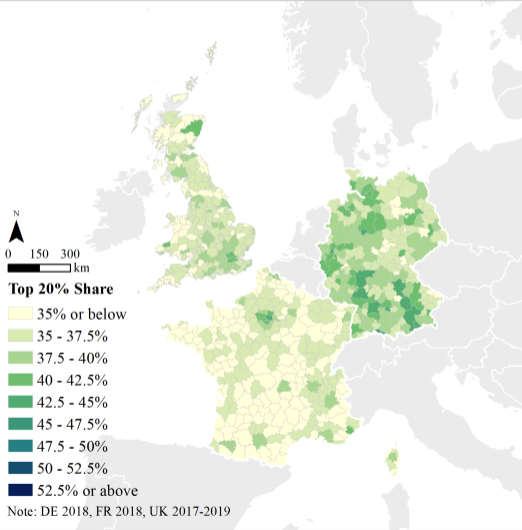

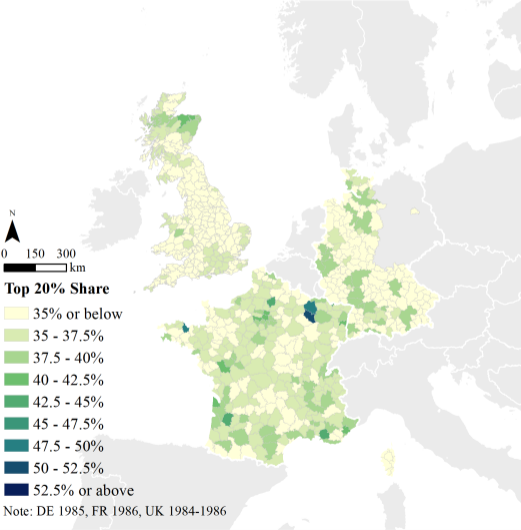

Number of employees

Illustrating our dataset: Within-area inequality in Europe

Illustrating our dataset: Within-area inequality in North America

Setting the scene: the rise in national wage inequality

Full-time workers, 20+ years old, weekly earnings. Source: UK: ASHE/NESPD; DE: SIAB; FR: DADS; CA: CCP; US: Census/ACS.

- The U.S. is the most unequal, France the most equal
- The highest increase in Germany (esp. 1995-2007) [◀ Go back](#)

Counterfactual national inequality: $\log(p_{90}/p_{10})$

- What would have the national inequalities looked like, if there had been no differences in the average wage across the regions?

$$p_{rt} = \frac{Y_t}{Y_{rt}}$$

- What would have the national inequalities looked like, if there had been no differences in the average wage across the regions?
- Policy equivalent → increasing average income tax in high-wage places and decreasing in low-wage places

Removing spatial inequality has almost no effect on wage inequality

Full-time workers, 20+ years old, weekly earnings. Source: UK: ASHE/NESPD; DE: SIAB; FR: DADS; CA: CCP; US: Census/ACS.

What is high spatial inequality: Reunified Germany

- Around reunification close to 0.05 (i.e., similar to the US today) [Go back](#)

Convergence/divergence: Median wages (p50)

Full-time workers, 20+ years old, weekly earnings. Source: UK: ASHE/NESPD; DE: SIAB; FR: DADS; CA: CCP; US: Census/ACS.

- Dispersion of median wages (p50) rather flat through time

p90 and p10 growth and initial city size: UK and US

The role of the largest LLMAs: US

- Dropping the largest LLMAs significantly lowers the rise of spatial dispersion of high wages (p90) but not of low wages (p10)

◀ Go back

Concentration: Share of FT workers in largest 5% LLMs (1980 = 0)

UK: share of population groups in the top-5% largest cities, 1980-2019
1980=0

US: share of population groups in the top-5% largest cities, 1980-2019
1980=0
